"ckepus@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Couldn't sleep tonight so went to the shack about 1 AM to fire up the 830S. Was tuning up on 40 but didn't get past step 1.

I was on a dummy load, Made sure the Heater switch was "on", Switched to 7 mhz, set mode to Tune, Meter to ALC, CAR to 1 3/4, Switched on SEND, peaked the Drive to about half scale, Then switched Meter to Ip, Mode still in Tune, :Prepared to dip Plate, switched to SEND, no Ip to dip!! Nada...;

Since I hadn't used the rig for transmitting since April - it was putting out full output then...(used it for a lot in the meantime - of listening while getting a B LIne up and running)... figured I must have done something dumb so rechecked everything...exercised the switches, and tried again.

Same result. No Ip, High voltage normal.

What suggestions for me when I begin troubleshooting tomorrow?

Tnx / 73 / Chris / W7JPG

Hello Mike,

After looking at several of the books that you recommended, I have to admit that I over looked a excellent source that I already had, The ARRL Handbook for Radio Communications. I will be doing a lot of reading in the next few months.
Of my rigs, the 830 has intermittent power out, and the 820 bias problems, so that leaves me with the 520 that is doing fine. I will get back to the group after doing some more reading.

Thanks again, Bob, KG6DHQ

Hi Dave,
Thanks for your suggestions.

There is no output in Tune or any other setting. I went through the whole tune up gig after a getting some sleep and, unfortunately, the results were the same as reported. Tried all bands, all modes, double checked settings, etc. No Ip.

Too many other items on the bench at the moment to tear into it.

Tnx,

You're welcome Bob. The older ARRL handbook editions tend to focus more on vacuum tube circuits with some solid state transistor/FET topics/discussions.

I said in a previous response that one can't service their KW hybrid if they have no clue how their KW hybrid side band transceiver produces and processes signals in both receive and transmit. You said you have a TS-520, well that's one of the easiest transceivers of the KW hybrid series to learn how side band works and how side band signals are processed in TX and RX.

Chris when your ready let us know.
Also check the sg switch on rear panel.
It could be the relay on AF board, known to cause similar problems.
Easiest way with right test equipment is to diagnose TIF circuitry to locate problem.

Chris:

Is this the radio with the 6293B finals?

Are you able to set the resting plate current to 60ma?

You do that in SSB mode,mic gain turned completely CCW, meter selector switch in IP, SG switch on, Heaters on, and flip to Send or PTT.

There is a web-based source advertising

8448 Tung-Sol branded Motorola "mobilized" version of the 12BY7A

for under four dollars a pop.

I've been looking for but not yet found the spec sheets for this tube. I have the spec sheet for the stock BY7A, and when I find the 8448 specs it will of course answer the question without recourse to the list, Being just as lazy as the next Schmoe, and while I'm trying to find the 8448 specs, I thought I might ask here.

Is this a reasonable replacement in a Kenwood hybrid (my 520SE specifically) for the 12BY7A driver tube? $3.75 plus a few more for shipping for NOS/NIB tubes, IF they are acceptable, sounds like a sweet deal to me.

If, however, they're not acceptable substitutions (and if I find the spec sheet I will post the location and the comparison here), then of course I don't want any. But the possibility of a low-cost spare driver does intrigue me....

So, anybody ever use one of these? Got a location for the specs? Anything? "Inquiring Hams want to know." (to mis-quote the tabloids)

> 8448 Tung-Sol

Found a short version of the 8448 data sheet right after I posted. As I said, here is the link to the PDF file. (NOTE: It will immediately give you a download of the PDF file. It isn't just a web page.)

https://frank.pocnet.net/sheets/127/8/8448.pdf

The same site has the 12BY7A standard tube data sheet from RCA here. (Same caveat about PDF downloads applies here.)

https://frank.pocnet.net/sheets/093/1/12BY7A.pdf

Looking at the two spec sheets, looks as if the 8448 should be a drop-in replacement for the 12BY7A, with absolutely no problems. Interelectrode capacitance and resistance values are identical. Likewise voltage, current, and power ratings. Sounds like the Russian BY7A knock-off (Tung-Sol is a Russian outfit, from long ago) should be just fine. And for less than four clams, I think I'll get a few for spares.

Does anyone have any contradictory information? Are the knock-offs just that - knocked off junk? In the past, some of the Russian kit I've used has been absolutely stellar. Some however has been anything but. Tung-Sol isn't in my list on either the good or bad side, so I'm soliciting input from the collected wisdom of this group.

So, Yay, or Nay?

Do I get a couple or not? (Ten bucks, either way, ain't gonna break me. It's not a "don't pay the mortgage" kind of decision, so there is no real pressure.)

(If there is not any prior information in the collective, perhaps I can provide some. Null data is still data, and I can Guinea-pig the driver tubes, see what happens.)

Wes,
"...Tung-Sol is a Russian outfit, from long ago ..."
Wikipedia says that Tung-Sol was founded in New Jersey in 1907 making light bulbs and similar. They later entered the tube business. I have several NOS Tung-Sol tubes and the boxes say "Made In USA".
Wiki did say that the Tung-Sol brand name is currently owned by the same company that owns the Sovtek brand name. I suspect that is a modern event.

Date: 2016-07-21 07:29:20 UTC
From: yellow_kite@...
Topic: 54852 Message: 55146

Ok. This is what happened next.

Rewound the L41. DC resistance tested OK on bench.
Borrowed a scope and injected signal at TP1
Output check at VC-S showed mixed results.
From 1.8 to 7.00 the output seemed OK. With 50 MV in the output was between 100 to 300 MV.
10 MHz and beyond no output.
Funny peak around 11.8 to 12.00 Mhz. Could not explain why.
At this point there was nothing more I could do.
Decided to put the board back into radio.

Now RF board is back in Radio. It works but only partially. Following status of calibrator signal across various bands.

1.8 MHz. S4
3.5 MHz. S8
7.0 MHz. S8
10.0 MHz. S1
14.0. MHz. S8
18.0. MHz. S8
21.0. MHz upwards S9

No realignment done. Only Q1 replaced with a 3SK73 very kindly loaned to me by VU2LO.

Nothing else touched. Operated radio on 14 SSB and CW and made few contacts. TX seems okay with about 90 watts output on 14. Only issue is that USB carrier Osc trimmer needs adjusting as audio reports indicated very sharp audio.

For the time being put the covers back on. Intend to use the radio as it is. Hopefully will have time to look into other bands specially 1.8 and 10 MHz.

Special thanks to Terry, K9TW for all support. To my friend. VU2ASB and VU2PPP for rewinding L41 and doing all the hard work.

Terry. My report is that the radio is slightly less semitones than it was before. Will it need to be realigned after replacing L41 ? I would think that L41 will have some effect on 1.8 MHz but on other bands it just acts as a broadband voltage step up transformer.

Thanks again Terry and all friends for valuable support. Last night worked 7Q7BP from Malwi. 599 both ways. 90 watts and a two element Quad.

Glad to see the analogue S meter dance again to S9 mark !!

You of course have to move the BS shaft as you test at each higher frequency and peak the response with VC-1, VC-2, and VC-3. With no rf output voltage at 10mhz it is possible not seeing the LC circuits due to bad contacts or not having the shaft accurately positioned ?

I would repeat the Coil Pack alignment.

David,
What is/are the problem(s) with your DG-1? Is it worth repairing...can't say as you have not stated what the problem(s) is/are. You stated that you followed the information on the net regarding the bad soldering on the display tube circuit board, and you could not find anything wrong. What did you do exactly? There are 18 "through holes" or "vias" that can cause problems on the DG-1 counter board (X54-1160-00). Just looking at the holes in question, will not tell you if they are indeed making a through connection to the other side of the board. Just reheating and re-flowing some solder on the holes may work...but it is recommended that you use a small piece of wire....clipped pieces of wire from resistors or caps..etc to insert into and through the holes in question while applying heat from your soldering iron/gun. A through inspection of the board and all its IC's is in order...use BRIGHT LIGHT AND HIGH MAGNIFICATION to look at ALL the pins/solder connections..looking for dry/cracked solder joints/connections.
When the DG-1 is malfunctioning..does the rest of the rig operate normally?...you did not say...Look at Page 40 of the TS-820S Service Manual...it gives you some basic diagnostic info. Some of the problems with the DG-1 can also be solved by good and careful cleaning of ALL the connections associated with it, including proper voltage (5V) from the voltage supply.....that little thing on stand-offs, big silver heat sink, big resistor,next to the DG-1

DG-1 in good operating condition do come on the market(EBAY) occasionally.
Your rig will work perfectly fine without the DG-1...just gotta do what hams have been doing for decades...use the analog dial...properly calibrated per the instruction manual..it's perfectly fine....a TS-820S without the DG-1 unit is called the TS-820...the predecessor of the TS-820S!

Topic: 55147 Message: 55150

David,
It sounds like you possibly did not check the correct circuit board.

Follow the cable from the display to the box located to the left side of the radio. Inside of the box are 2 boards. The board in question is the closest to the outside of the cabinet, or farthest away from the display. Kenwood has several service bulletins, #26 & #53 dealing with the subject. You can read them here:

http://wb4hfn.com/KENWOOD/Articles/SERVICE%20NOTES%20-%20ALL%20HYBRIDS.pdf
http://wb4hfn.com/KENWOOD/Articles/SERVICE%20NOTES%20-%20ALL%20HYBRIDS.pdf

There were also several slides dealing with this subject given at this years Dayton Hybrid Forum. Pages #77-79 from the following PDF deal with this subject.

http://wb4hfn.com/KENWOOD/Hamvention/KENWOOD%20FORUM%202016.pdf
http://wb4hfn.com/KENWOOD/Hamvention/KENWOOD%20FORUM%202016.pdf

I've had several TS-820S and R-820's, all with display problems and the above referenced material has fixed every one of them. So it's worth spending a little extra time and cover all your bases.

Good luck and good reading.

Mark, WB0IQK

55151. TS-830S final failure

Yahoo group: TS-520_820_530_830 (2015 — 2016)

The final failure was typical and predictable . Screen and cathode resistors , plate choke , and ...

The recently repaired HV supply survived . How ever I have a curious symptom that I'm hoping is familiar .
The VFO rests at the bottom of each band
160m = 1.000
80m = 3.000
40m = 6.500
30m = 9.500
etc...

Just seeing if anyone has seen this symptom and could save me some time .

Topic: 55151 Message: 55152

I think you are saying that the Digital Display is 500 khz off (low) when the analog VFO is set to Zero. If so, it appears you have lost the Counter Input signal (CON). You can try wiggling Molex Conn 3 on the PLL board and/or Molex Conn 2 on the Counter Unit board.

If you have an O-scope can measure the CON at the PLL Board and the Counter Unit board. Will be from 500khz to 1.0 mhz depending on where you have set the VFO. For example if the VFO is set to 250 on the analog dial the CON will be 750khz and approx 250mv to 300mv P-P sine wave. If the VFO is set to 500 then it will be 1.0 Mhz and same level.

Loss of CON has nothing to do with loss of Final tubes or PA cage or Final board components.

Hi Dennis,

I think you're describing a problem similar to one I had some time back. For me it turned out to be the FIX switch. Try pushing it in and out a dozen or more times and see if you get a change. If so, you may have to spray the switch with Deoxit which is not that easy. It's hard to get at.
I pulled the face off my 830, stood the radio on it's rear and carefully dribbled DeOxit into the shaft area. I then worked the switch and blew out excess with compressed air. Before doing this, I stuffed some chunks of paper towel below and around the switch to prevent getting excess spray into the radio.

Hope this helps,
Kevin - N2FLP

Topic: 55154 Message: 55155

Bob,
The KW hybrids, whether it's a TS-520 TS-530, TS-820 or TS-830 transmitters are all tuned the same. All of the KW hybrids have the same Class AB1 final amplifier.

Connect the 820 or 830 to your 50 ohm dummy load. To make it easier, pull any CW key plug from the rear panel CW key socket.

Power up the transceiver and allow it to warm up for at least 30 minutes.

1. Set Meter to ALC2. Set the MODE switch to TUNE. This setting reduces the final tube screen voltage by 47%, resulting in less stress on the final tubes.
3. Set the LOAD control fully CCW and the PLATE control so the knob points within the white silk screen on the front panel based on the band switch setting4. Set the DRIVE control to 12 o'clock5. Set the CAR control to 12 o'clock6. Flip SEND switch UP, keys the transmitter.7. Adjust the DRIVE control for a peak meter indication. You do not need to be concerned about exceeding the top of the ALC scale. If the meter pegs fully to the right adjust the CAR control CCW so the meter pointer drops back to 11 o'clock and continue adjusting the DRIVE control for a peak meter indication.8. Set meter switch to IP and adjust the PLATE control for a DIP in IP current (adjust for lowest IP meter indication).9. Flip the SEND switch down (unkeys transmitter) then set MODE switch to CW.10. Set Meter switch to REL PWR.11. Flip SEND switch UP and adjust the LOAD control for a peak meter indication. If meter pegs fully to the right, adjust the rear panel RF VOLT pot (820, 530 830 or the RF voltage on the side panel on the 520 series transceivers) so the meter drops back to 11 or 12 o'clock and continue adjusting the LOAD control for a peak meter indication. Once the LOAD control is adjusted for maximum meter indication, adjust the RF VOLT pot so the meter points between 1 and 2 o'clock. The REL PWR meter has no scale and it is not watt meter.
12. Set meter switch to IP and, if necessary, adjust the CAR control so the IP meter does not exceed 220ma for the 520 or 820 and 250ma for the 530 or 830.13. Flip the SEND switch DOWN, unkeys the transmitter, you're done!!
If you do not have a 50 ohm dummy load with a power rating at least twice or higher of the transmitter, I highly recommend you purchase one and use it when you tune your transmitters.

Subject: [TS-520_820_530_830] Another question

Hello Mike, I was looking at the transmitter tuning for the 820...mode switch, tune, meter/IP, dip the
plate
830...mode switch, tune, meter/RF, peak the RF with the plate control This is confusing to me. I understand dipping the plate, but is peaking the plate in RF the same ?

Thanks Terry

Now that RF board is in radio, the shaft is moving. I am giving the radio some time. My basic question is this. Is it possible for coil pack to go out of alignment by simply changing a new L41 ? Will look into band switch connections carefully to ensure there is no bad contact.

But On transmit ALL bands work 100 % OK with full drive !

We have a winner ! Kevin N2FLP .
Trashing and bashing the fix switch did the trick .
You saved me the arduous task of verifying all the primary voltages and signals .
Anyone that has performed a complete service and alignment doesn't have to estimate the time that takes .

Thank You Kevin and Terry for your responses

55158. Diagnosing a TS-830S frequency counter display problem

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-07-22 08:08:26 UTC
From: john
Topic: 55158 Message: 55158

Just unboxed a TS-830S. It tunes and transmits but does not display anything in the frequency counter display.

I've cleaned and re-seated all the connectors with no luck. Based on reading it sounds like the board frequently has bad connections due to solder problems. Is there a way i can check the display? I suspect that the display itself may be the problem. I noticed a small spot on the right side of it that might be a short or burn.

Any recommendations are appreciated.

Thanks

Thanks Mike.....I followed your transmitter tune up instructions and the 830 was working. I was seeing about 35/40 watts on 40 meter cw. I tapped out a few letters and suddenly the power out dropped to zero. I went back and looked at the IP. I had adjusted it down to 220 ma and now it was off scale. It adjusted it back down to 220 ma, but there was on longer any output. I guess I still have some sort of problem with my TS-830S.

I'll bet you have a bad antenna relay or the relay is not switching.
I have seen that behavior (Ip pegged in the right corner) in my 530 and
the relay was bad.

OK, warmed up the 830 for about an hour. I went through the tuning procedures trying 20/40/80 meters, with no power out. I am operating through a Diawa SWR meter into a 600 watt dry dummy load. Set the rig to CW, push my key, I hear the tone, but the needle on the Diawa meter does not even quiver ! I checked the meter using my Icom 756 and it works fine on that rig.
I need to mention that I replaced the tubes with 6146W’s that I got at a Ham swap meet. I did try to neutralize them using a second receiver. I did not see much dip, but set it for the lowest reading.

>
> Bob, KG6DHQ

Put the original 6146B's BACK in the sockets. Don't worry about neutralizing yet. Check for output. Report back. If you allasudden get some output on your nice, working, Wattmeter, THEN neutralize your old tubes, get your money back on the 'Ws, and look into some new B's if your old ones are really failing.....

Group,
The email address does not belong to a member of our group as far as I can determine...but PSE practice due diligence with suspect emails. We try had to make sure that all group info stays secure...but once someone becomes a member there is a good amount of info that can be had, just by everyday msg/post traffic. Over the past few months, I have been filtering group membership requests....and have rejected numerous suspect requests. I ask person to verify their name, call(including class) and their qth, even though they may have already provided it in the "join screen." If no reply..request is summarily rejected. If the request is from a non-ham(allowed), they need to supply full name and qth info..that I keep in a separate file along with their email addresses. Most recently...like today...a person wanted to join. I requested the above stated info..as the only thing this person put in the "join" are was: "I want to buy a TS-830." His response was that his "personal information was none of mine or yahoo's business...and he's insulted with my "data mining" and he goes on to sign off with: PS: this is still America...not run by you, Facebook, Google, or Yahoo.
I was happy to reject his membership request...he would not have been able to follow our group policy anyway....
  Stay digitally safe....and TNX WES-n9ktd

If your FIX switch was depressed the Digital Display should have been blank and not 500khz low?

This is because the regulated 9vdc to the VFO is switched off and the 9vdc to Q37/Q38 Crystal Oscillator is turned on via FXB.

With the VFO turned off and no crystal in the socket on the PLL board there would be no 5 mhz to 6 mhz signal supplied to Q40 Mixer.

I did not understand that the display was blank?

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by Jimmy, WB2KNR. There
were 10 stations checking in under very poor band conditions.

We had the following number of radios checking in.

4 running TS-520(x)
0 running TS-530(x)
0 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running TS-515
0 running 599 twins
0 running TS-900

He was running his TS-520.

The Sunday net was run by me, WB0IQK. There were
21 stations checking in under very poor band conditions.

We had the following number of radios checking in.

1 running TS-520(x)
1 running TS-530(x)
3 running TS-820(x)
4 running TS-830S
0 running TS-510
0 running TS-511
1 running 599 twins
0 running TS-900

I was running my TS-520s + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940â□□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 ☐ Oct 2015 Saturdays total 9962 check-ins, Sunday total 669 check-ins

November 2015, Saturday net total = 66, Sunday total = 46
December 2015, Saturday net total = 55, Sunday total = 73
January 2016, Saturday net total = 129, Sunday total = 81
February 2016, Saturday net total = 98, Sunday total = 72
March 2016, Saturday net total = 74, Sunday total = 35
April 2016, Saturday net total = 101, Sunday total = 57
May 2016, Saturday net total = 51, Sunday total = 32
June 2016, Saturday net total = 39, Sunday total = 46
July 2016, Saturday net total = 42, Sunday total = 48 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Ditto on that same topic.
I think it was back in May the last time that I heard Mark. However, I was able to check into the Heathkit net on 20M (14.292.5 MHZ at 2 pm central standard time), for the first time.
Very strange propagation going on.
Oh, just a reminder that the vintage tube net is _this coming Monday, on 3.938 at 8:00pm Eastern_. Three tubes or more and you can check in.
Jan N8CBX

Terry:
Thanks for the advice on the "no ALC no transmit" on the TS-820s recently. I ordered the parts and then built a homebrew version of the old Heathkit PK-3 probe over the weekend. Found the schematic on the internet. It's a 3-diode probe. Also received the 1-diode RF sniffer in the mail. Hope to do some RF sniffing this weekend when I get back home.

Subject: RE: [TS-520_820_530_830] Re: No ALC or Transmit TS-820

Larry:Just remember if it is a single diode germanium or schottky diode probe as most commercial RF probes are you will be able to use if for such common tasks as:Product Detector carrier null, Balanced Mod LSB/USB carrier suppression balance, Final Tube neutralization, TIF signal measurement, Transmit Mixer output measurement, VFO output level adjustment, VCO level, Carrier Oscillator level adjustment etc. However, you WILL NOT be able to use it to measure the output of the 12BY7A Driver tube or the RF drive at the control grids of the 6146 or S2001A Final tubes. The only way you could use it to detect the presence of RF at the 6146 final tube control grids would be to set CAR Level pot full CCW, connect RF probe to control grids, slowly advance the CAR Level pot CW until you read no more than approx 30 rms RF volts. This would tell you that you had RF drive to your final tubes, but wouldnt be able to tell if you have enough for ALC indication.I woudnt use the probe in this manner unless you know for certain what signal diode it uses as you risk burning out the diode. At 30 rms RF volts the reverse voltage that your probes diode is seeing is approx 30 x 2.83 = 85 volts. A 1N270 has a PIV of around 90 volts. A 1N34 has a PIV of approx 65 volts. Kiss the 1N34 good bye!When you obtain your probe and if you need help running TX Level Diagram come back and ask.Terry K9TW

blockquote, div.yahoo_quoted { margin-left: 0 !important; border-left:1px #715FFA solid !important; padding-left:1ex !important; background-color:white !important; } I have finally got round to replacing the driver and finals including neutralising them in my 830m but there still seems to be a few problems. I have had a good read of the manuals and would appreciate any thoughts from anyone who might have encountered something similar. The cathode resistors all measure around 5ohms. 20m tunes up ok and provides 100w out.
1) when in tune mode and the meter is switched to IP I get no reading on the meter on any bands when in send
2) ALC seems to register fine on all bands apart from 10m - on 10m I can get no ALC reading in tune or cw modes and no RF out. 10m still receives fine and I can hear relay activation when I try to send

On Tuesday, July 12, 2016 8:02 PM, "Mike W5RKL w5rkl@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Â Laurie,

The typical CW transmit frequency "shift" as seen on the digital display is approximately 800Hz which is normal. It's possible you may be reading the digital display incorrectly. Note the CW "receive" frequency indicated on the digital display. Next, key the transmitter in CW mode and note the "transmit" frequency indicated on the digital display. Subtract the transmit digital display frequency from the receive digital display frequency which is the CW transmit "shift" that is occurring.

There will be no transmit frequency "shift" when operating side band.

You say the 830 produces normal 100 watts output on side band on all band, slightly less on 10, that's normal. I am going to assume CW transmit produces the same 100 watts output on all bands, slightly less on 10 meters as well.

You said "there is almost no IP reading in TUNE mode on any band". You then said "IP seems to register normally under CW".

Do you have the meter switch set to ALC in TUNE mode?

Perform the following initial transmitter tuning steps:

1. Set meter switch to ALC
2. Set band switch to say 40 meters
3. Set Mode switch to TUNE
4. Set DRIVE control to 12 o'clock
5. Set CAR control between 10 and 11 o'clock
6. Connect the 830 to your 50 ohm dummy load
7. Power up the 830 and allow it to warmup for 30 minutes
8. Flip the SEND switch UP (Keys transmitter)
9. Adjust the DRIVE control for a peak meter indication, ignoring all meter scale. If the meter pegs fully to the right, rotate the CAR control CCW so the meter drops back to 12 o'clock or so, then continue adjusting the DRIVE control for a peak meter pointer indication.
10. Once the ALC peak meter pointer indication in TUNE mode is achieves, leave the transmitter keyed for a couple seconds longer while monitoring the meter. If the meter pointer starts to drop back towards zero then the driver tube is weak and should be replaced. If the meter peak remains stable, does not drop back towards zero, then the driver tube can be considered okay. I could be wrong but I suspect, at leas for now, the driver tubes is okay.

This is the initial driver adjustment for maximum RF drive to the final amplifier and a quick way to check the driver tube.

A "dead" driver tube has no control or affect over the final amplifier's 60ma idling current.

A "dead" driver tube has nothing to do with the CW transmit shift seen on the digital display.

A "dead" driver tubes would not produce 100 watts output, as you said, on side band and as I assumed also on CW.

Â Hi All

I was hoping that someone with more experience of the TS-830 might be able to advise me with a few issues that seem to have recently taken place on my TS-830M.

1) There is almost no IP reading when in TUNE mode on any band (IP seems to register normally under CW) 2) There is almost no ALC or IP reading on 10m in any mode (and no power output on this band)
3) When in receive and switching from TUNE to CW the frequency counter reading increases by about 5khz. 4) When keying down in CW on any band the freq counter reading instantly increases by about 10khz (it drops back again when not transmitting)

I have tried replacing the finals and have the same issues. I have checked that all the switches are in correct positions and tried cleaning them with a dash of deoxit. I have checked the bias and the grid current is set at 60mA. In sideband the radio still provides 100w on all bands apart from 10m and has no frequency shift when transmitting. I am wondering could much or all of this be caused by a dead or dying driver?
many thanks and 73 Laurie G0LTG

From: Mike W5RKL
Topic: 55194 Message: 55203

Larry,

An overheating R14 on the Rectifier Unit board can quite often be caused by a shorted C6, 33ufd 160VDC, bias supply filter capacitor!! A shorted C6 will result in loss of the "-C" bias supply. Therefore, until you determine whether C6 is actually shorted, do not power up the 830!!

Do you have the TS-830 operator and service manuals plus the high resolution TS-830 schematic? If not then you can download them all at my website by clicking the following links:

TS-830 Operator's Manual:
http://w5rkl.com/wp-content/uploads/2014/04/TS-830-operators-manual.pdf

TS-830 Service Manual:
http://w5rkl.com/wp-content/uploads/2014/04/TS-830_Service_manual.pdf

TS-830 High Resolution Schematic:
http://w5rkl.com/wp-content/uploads/2014/04/TS-830S-excellent-schematic.pdf

If you look at the TS-830 high resolution schematic, C6 on the Rectifier Unit, you will see if C6 is shorted internally to ground that R14 will then be connected directly to ground causing excessive current to flow through R14 resulting in R14 to over heat and "burn up" when the 830's powered up. This results in loss of "-C" bias supply voltage to the 830.

VOX issues.Is this just an issue when you try to use VOX control, and normal voice transmission when you press PTT on the mic?? I would check the mic PTT switch wiring and make sure you have continuity for the audio path to the mic connector when the PTT switch is not pressed. You may have to solder a jumper across the audio contact on the mic if there is an open contact there.Good luck. My radio is Ham Radio...CW is Real Radio 73, John...K8JD

Hi John.(K8JD)...I knew it was just a case of being overlookedThis is the re post....

Hi folks..... Been a while since I bothered you..... I just tried turning on my VOX control on my ts830......No go.... I just get a relay click every now and then while I turn the gain up or down. This does turn the audio off when the relay clicks but NO transmit.. NO response from microphone on any setting of gain...Usual question.... Where do I start to look..?? I DID replace the relay on the AF-AVR unit a while back.....Did I NOT do good job ???No big deal on VOX for me. I just want to get it working for my own piece of mind.. Thanks for any help you can provide.

Mike,

The PC board foil runs and pad are rather fragile and easily broken when replacing components by applying heat.

I had a similar problem when I replaced a relay in a TS-120, same relay used in the TS-830. I thought everything was okay as I checked the solder connections for shorts etc. What I did NOT check, I learned from this mistake, was I didn't check each relay pin foil pad and foil run from the pad for continuity. I found "1" relay pin foil pad and foil run that had a crack causing loss of connection resulting in the meter not working. Once the break in the pad to foil run was repaired the meter worked. I recommend you do that, check each relay pin pad to foil run to ensure there is continuity in all of them. It only takes one pad to foil run to be broken to cause a problem.

  Larry,

An overheating R14 on the Rectifier Unit board can quite often be caused by a shorted C6, 33ufd 160VDC, bias supply filter capacitor!! A shorted C6 will result in loss of the "-C" bias supply. Therefore, until you determine whether C6 is actually shorted, do not power up the 830!!

Do you have the TS-830 operator and service manuals plus the high resolution TS-830 schematic? If not then you can download them all at my website by clicking the following links:

TS-830 Operator's Manual:
http://w5rkl.com/wp-content/uploads/2014/04/TS-830-operators-manual.pdf

TS-830 Service Manual:
http://w5rkl.com/wp-content/uploads/2014/04/TS-830_Service_manual.pdf

TS-830 High Resolution Schematic:
http://w5rkl.com/wp-content/uploads/2014/04/TS-830S-excellent-schematic.pdf

If you look at the TS-830 high resolution schematic, C6 on the Rectifier Unit, you will see if C6 is shorted internally to ground that R14 will then be connected directly to ground causing excessive current to flow through R14 resulting in R14 to over heat and "burn up" when the 830's powered up. This results in loss of "-C" bias supply voltage to the 830.

Mike,

I'm not sure you understood what John meant in his message.

Quote from John; "I would check the mic PTT switch wiring and make sure you have continuity for the audio path to the mic connector when the PTT switch is not pressed."

Some mics have a VOX setting and some have to be modified. For VOX to work correctly, the audio path needs to be complete, even when the PTT switch is not pressed. Testing the mic in SSB mode may work fine because the PTT switch is connecting the audio path as well as closing the radio relay for transmit. That does not mean it will work when in VOX mode and the switch isn't pressed.

If you already knew this, never mind (-:

Hope this helps,
Kevin - N2FLP

Don't. It gets a lot worse than this. In high school electronics shop, we had several superior specimens of homo sap, subspecies doofus supremus.

YOU at least listened, checked, and found the real issue WITHOUT disassembling your entire radio or something equally silly.

I watched one of the aforementioned doofii take an entire (tube) television apart on the bench, unable to figure out why NOTHING worked at all, and then being quite upset - AT ME - when I handed him the plug end of the power cord, "It might work better with some electricity....".

Hi All,

One thing I've noticed with this discussion which
has nothing to do with radio is the topic name
keeps changing. For someone that comes along well
after this discussion is over they may not find
all the parts of the discussion if they do not search carefully.

This discussion has five topic names

ts 830 vox problem 1 post
VOX... 4 posts
Vox... 4 posts
VOX issue... 2 posts
VOX..... 5 posts

Of course all have the word VOX in them but the
posts do not "thread" together to keep the
discussion under one heading. Ever wondered where
the term "thread' came from? Now Yahoo! call a
discussion a topic or conversation but it's the
same thing. I'm sure it would help those that
come later if the topic remained the same for the
whole of the discussion. Another good thing about
keeping the topic name the same is seen if the
discussion is very active. It will appear in the
trending topics window (just below the new topic
button) and make it easy to find the next time you come back to the group.

So who controls the topic names? Quite rightly
it's the guy who starts the conversation. If he
keeps going back to reply to the most recent post
in his original topic rather than hitting the new
topic button, and if all of us reply to the same
topic name that our guy started, the whole
discussion (topic/conversation) will thread
together and be available to those looking for the same help.

Posted in the interest of helping out and making information easier to find.

Regards

Lou

This is the current status

Freq S Meter Calibrator Signal ALC Level Max Drive 1.900 5 9 3.700 6 8 7.100 9 6 10.150 3 8 14.175 7 8 18.150 7 0 21.250 8 0 24.750 9 0 28.400 8 0 29.400 7 0

Drive Control at 12 O Clock

Carrier Max

SG OFF

Antenna Connected

It is Obvious

20 and 7 are working mostly OK
Poor reception on Lower Bands
No Transmit on 17 M and above

I did not clean the band-switch before putting radio back. To the best of my memory, all bands were working 100 % OK on RX and TX before I lost L 41.

I should be happy with current status as 40 and 20 are the bands of my interest. Still, any suggestions Terry ?

Have you performed a complete Coil Pack Alignment as directed in the Service Manual. I often find the Drive coils grossly mis-adjusted. If done properly max ALC indication (RF drive) should occur at very near same peak in receiver background noise or marker signal level.

Do the Ant and Mixer coils in Rx mode first and then do the Drive coils. I have the SM Step 14 procedure explained in detail on my website.

Terry K9TW

Any band where you are showing "0" ALC indication while peaking the Drive with the CAR Level Pot full CW I would measure the RF drive voltage.

Need O-scope, RF millivolt meter, or RF probe and VTVM. Could start at the Control Grids of the 6146 Final tubes and work back to the TIF amp if needed.

For example on 21.250 mhz connect RF voltage measuring test gear to Pin 5 and see if any RF voltage exist when flip to Send. Do this with the SG switch off as no need to engage the Finals beyond cathode emission and operating bias voltage. If you see RF voltage try peaking the 21 mhz Drive coil (white) for maximum RF voltage. This assumes you have done the Ant and Mixer coils first.

Anything below around 42 rms rf volts there will be no ALC indication (assumes -60vdc bias).

Mike,

You said:

/"//I AM getting into PSK31 cause I can use keyboard..... SO THERE! (Not with 830, need low power with that digital stuff)..//"/

From that statement, it appears you think you can't operate the TS-830 at low power. If so then you are mistaken. You can operate PSK at low power using your TS-830, you simply do the following:

1. Tune the TS-830 up for normal side band voice operation, including setting the MIC gain for normal ALC voice peak indication to not exceed the top of the ALC scale. At this point you will NOT touch the MIC gain to control PSK power output!!

2. Connect your PSK sound card interface to the TS-830 and make ALL PSK transmit audio level adjustments for power output by adjusting the PSK sound card interface transmit audio pot, NOT the TS-830 MIC gain!!! Adjust the sound card interface for a power output of approximately 20 to 25 watts. The TS-830 ALC meter in transmit should never show any ALC when operating PSK!!!

That's all there is to operating PSK low power using your TS-830 and a sound card interface. Most sound card interfaces have the option of using either PTT or VOX to key the transmitter. I recommend VOX since VOX does not require PTT wiring from the sound card interface to the TS-830. You will have to use the PSK software "configure" settings for VOX instead of PTT. Simply follow the sound card interface and PSK software instructions, it's rather easy.

Although I haven't been on PSK in quite a while, when I did operate PSK I used an MFJ-1275 sound card interface with my Yaesu FT-757GX. I use VOX which reduced the number of cables between the MFJ-1275 and the FT-757GX. The MFJ-1273BT has the "round 4 pin" mic socket connections, the MFJ-1273BT includes the mic cable and other TX and RX cables to connect between the 1273BT interface and the computer sound card and the TS-830. You simply have to set the internal jumpers to the transceiver, instructions included with the 1273BT.

I have also built my own sound card interface before purchasing the MFJ-1275 interface. It's easy, inexpensive, and all the components, perforated boards, and cabinets can be found on eBay or other on line parts outlet sources.

I have finally got round to replacing the driver and finals including neutralising them in my 830m but there still seems to be a few problems. I have had a good read of the manuals and would appreciate any thoughts from anyone who might have encountered something similar. The cathode resistors all measure around 5ohms. 20m tunes up ok and provides 100w out.
1) when in tune mode and the meter is switched to IP I get no reading on the meter on any bands when in send
2) ALC seems to register fine on all bands apart from 10m - on 10m I can get no ALC reading in tune or cw modes and no RF out. 10m still receives fine and I can hear relay activation when I try to send

I was a bit vague on my last response.

Repeat the initial TUNE mode DRIVE control transmitter tuning for an ALC meter peak indication but do it on 40 meters. If the peak ALC meter indication in TUNE mode starts to drop back "on its own" toward zero then replace the driver tube.

Â Hi Mike

Thank you very much for your help. Yes my mistake on the freq change, when I key down on CW as an example the freq display will change from 14.299.0 to 14.299.9 similar to the 800hz you mention. I have only recently started using the radio for CW so its quite likely that I just didn't pick up on this before.
I've had another look this evening and when in TUNE mode there is no IP reading on any band. On 10m in TUNE mode the ALC reading rapidly falls from a low value to near zero and negligable RF power out on CW.

many thanks & 73Laurie G0LTG

On Tuesday, July 12, 2016 8:02 PM, "Mike W5RKL w5rkl@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Â Laurie,

The typical CW transmit frequency "shift" as seen on the digital display is approximately 800Hz which is normal. It's possible you may be reading the digital display incorrectly. Note the CW "receive" frequency indicated on the digital display. Next, key the transmitter in CW mode and note the "transmit" frequency indicated on the digital display. Subtract the transmit digital display frequency from the receive digital display frequency which is the CW transmit "shift" that is occurring.

There will be no transmit frequency "shift" when operating side band.

You say the 830 produces normal 100 watts output on side band on all band, slightly less on 10, that's normal. I am going to assume CW transmit produces the same 100 watts output on all bands, slightly less on 10 meters as well.

You said "there is almost no IP reading in TUNE mode on any band". You then said "IP seems to register normally under CW".

Do you have the meter switch set to ALC in TUNE mode?

Perform the following initial transmitter tuning steps:

1. Set meter switch to ALC
2. Set band switch to say 40 meters
3. Set Mode switch to TUNE
4. Set DRIVE control to 12 o'clock
5. Set CAR control between 10 and 11 o'clock
6. Connect the 830 to your 50 ohm dummy load
7. Power up the 830 and allow it to warmup for 30 minutes
8. Flip the SEND switch UP (Keys transmitter)
9. Adjust the DRIVE control for a peak meter indication, ignoring all meter scale. If the meter pegs fully to the right, rotate the CAR control CCW so the meter drops back to 12 o'clock or so, then continue adjusting the DRIVE control for a peak meter pointer indication.

10. Once the ALC peak meter pointer indication in TUNE mode is achieves, leave the transmitter keyed for a couple seconds longer while monitoring the meter. If the meter pointer starts to drop back towards zero then the driver tube is weak and should be replaced. If the meter peak remains stable, does not drop back towards zero, then the driver tube can be considered okay. I could be wrong but I suspect, at leas for now, the driver tubes is okay.

This is the initial driver adjustment for maximum RF drive to the final amplifier and a quick way to check the driver tube.

A "dead" driver tube has no control or affect over the final amplifier's 60ma idling current.

A "dead" driver tube has nothing to do with the CW transmit shift seen on the digital display.

A "dead" driver tubes would not produce 100 watts output, as you said, on side band and as I assumed also on CW.

On 7/12/2016 5:30 AM, Laurie J g0ltg@... [TS-520_820_530_830] wrote:

Â Hi All

I was hoping that someone with more experience of the TS-830 might be able to advise me with a few issues that seem to have recently taken place on my TS-830M.

1) There is almost no IP reading when in TUNE mode on any band (IP seems to register normally under CW)2) There is almost no ALC or IP reading on 10m in any mode (and no power output on this band)
3) When in receive and switching from TUNE to CW the frequency counter reading increases by about 5khz.4) When keying down in CW on any band the freq counter reading instantly increases by about 10khz (it drops back again when not transmitting)

I have tried replacing the finals and have the same issues. I have checked that all the switches are in correct positions and tried cleaning them with a dash of deoxit. I have checked the bias and the grid current is set at 60mA. In sideband the radio still provides 100w on all bands apart from 10m and has no frequency shift when transmitting. I am wondering could much or all of this be caused by a dead or dying driver?
many thanks and 73Laurie G0LTG

"I AM getting into PSK31 cause I can use keyboard..... SO THERE! (Not with 830, need low power with that digital stuff).."
From that statement, it appears you think you can't operate the TS-830 at low power. If so then you are mistaken. You can operate PSK at low power using your TS-830, you simply do the following:

1. Tune the TS-830 up for normal side band voice operation, including setting the MIC gain for normal ALC voice peak indication to not exceed the top of the ALC scale. At this point you will NOT touch the MIC gain to control PSK power output!!

2. Connect your PSK sound card interface to the TS-830 and make ALL PSK transmit audio level adjustments for power output by adjusting the PSK sound card interface transmit audio pot, NOT the TS-830 MIC gain!!! Adjust the sound card interface for a power output of approximately 20 to 25 watts. The TS-830 ALC meter in transmit should never show any ALC when operating PSK!!!

That's all there is to operating PSK low power using your TS-830 and a sound card interface. Most sound card interfaces have the option of using either PTT or VOX to key the transmitter. I recommend VOX since VOX does not require PTT wiring from the sound card interface to the TS-830. You will have to use the PSK software "configure" settings for VOX instead of PTT. Simply follow the sound card interface and PSK software instructions, it's rather easy.

Although I haven't been on PSK in quite a while, when I did operate PSK I used an MFJ-1275 sound card interface with my Yaesu FT-757GX. I use VOX which reduced the number of cables between the MFJ-1275 and the FT-757GX. The MFJ-1273BT has the "round 4 pin" mic socket connections, the MFJ-1273BT includes the mic cable and other TX and RX cables to connect between the 1273BT interface and the computer sound card and the TS-830. You simply have to set the internal jumpers to the transceiver, instructions included with the 1273BT.

I have also built my own sound card interface before purchasing the MFJ-1275 interface. It's easy, inexpensive, and all the components, perforated boards, and cabinets can be found on eBay or other on line parts outlet sources.

Terry K9TW :
Terry
I have completed my measurements of using the transmit level page from the ts 820s service manual and your suggestions. Used the 1-diode rf sniffer on most of it and the 3-diode probe that I built on just the 12BY7 driver and the 6146. Had the freq on 14.175 and carrier control fully clockwise. Read the voltages on the 0 to 20 volt readout on DMM. May be some error in trying to figure where a component's lead side was on the trace side.

Anyway, here's what I got in "Send" position:
RF Board--
TIF .29v
Q1-Q8 drains .13v
Pin #7 12BY7 -.9v
Pin #5 6146 -.5
C1 to T1 .13v
IF Board--
Q1 to T1 .67v
D6 to Q1 .06
D5 cathode toT4 .10v
C92 to T4 -.33v
C92 to Q18 -.51v
C87 to Q18 -.04v
VR5 center? .40v
VR5 2 other points .36v & .35v
TP2 0v
Hope I did this correctly and your further suggestions will lead me in the direction of fixing the 820. I can't thank you enough for your advice.

Subject: RE: [TS-520_820_530_830] Re: No ALC or Transmit TS-820

Larry:Just remember if it is a single diode germanium or schottky diode probe as most commercial RF probes are you will be able to use if for such common tasks as:Product Detector carrier null, Balanced Mod LSB/USB carrier suppression balance, Final Tube neutralization, TIF signal measurement, Transmit Mixer output measurement, VFO output level adjustment, VCO level, Carrier Oscillator level adjustment etc. However, you WILL NOT be able to use it to measure the output of the 12BY7A Driver tube or the RF drive at the control grids of the 6146 or S2001A Final tubes. The only way you could use it to detect

the presence of RF at the 6146 final tube control grids would be to set CAR Level pot full CCW, connect RF probe to control grids, slowly advance the CAR Level pot CW until you read no more than approx 30 rms RF volts. This would tell you that you had RF drive to your final tubes, but wouldnt be able to tell if you have enough for ALC indication.I woudnt use the probe in this manner unless you know for certain what signal diode it uses as you risk burning out the diode. At 30 rms RF volts the reverse voltage that your probes diode is seeing is approx 30 x 2.83 = 85 volts. A 1N270 has a PIV of around 90 volts. A 1N34 has a PIV of approx 65 volts. Kiss the 1N34 good bye!When you obtain your probe and if you need help running TX Level Diagram come back and ask.Terry K9TW

Topic: 54481 Message: 55234

Welcome to the Yahoo Kenwood TS-520_820_530_830 Amateur Radio Group. This group is comprised of members who's interest is in maintaining and operating the Kenwood TS-520, TS-820, TS-530, TS-830, TS-510, TS-511, T-599/R599 and R820 Hybrid transceivers, transmitter and receivers. In addition, the group supports discussions covering the associated Kenwood accessories such as the VFO-520, VFO-820, VFO-230, and VFO-240 remote VFOs, the Kenwood antenna tuners, and the various Kenwood desk and hand microphones.

This is a restricted group requiring membership approval prior to receiving and posting messages to the group. To join the group simply complete the Yahoo Kenwood TS-520_820_530_830 Group's application process by clicking on the “+ Join Group” icon on the group's homepage. Select the desired method of receiving messages by clicking the appropriate radio button, then provide a brief description about yourself to include: your first name, your Amateur Radio call sign, your interest in the Kenwood hybrid radio, and the model of Kenwood hybrid you own, operate, or in the process of purchasing in the text box provided. If you are not a licensed Amateur Radio operator, no problem, simply complete the application process and provide the same information less the Amateur Radio call sign. Once you have completed the text, click the Join Group icon. Your application will be reviewed and approved by a group co-owner or Moderator. If you leave the application text box blank, your application for membership will be rejected. Simply reapply and provide the information requested and resubmit your application for membership.

New members are placed on a "Moderate" status. This means that any message a new member posts to the group must be approved by a group co-owner or Moderator before it appears on the group server for all members to see. The length of time a new member remains in a "Moderate message status" is determined by the members ability to adhere to, and follow the group's policies. The faster the new member(s) can prove they are adhering to, and following the group's policies, the quicker the new member's status will be changed to “Allowed”.

The “Allowed” status means the member can submit/post their messages without group co-owner or Moderator's approval. A member who's message status is set to “Allowed” may have their message status changed to "Moderate" if it is deemed necessary by a group co-owner or Moderator for one of the following reasons:

1. Failure to follow the group's policies after being informed by a group co-owner or Moderator
2. Knowingly violate any of the group's policies
3. Any improper behavior by the member that is deemed inappropriate by a group co-owner or Moderator

The group is moderated by both group co-owners and group Moderators. While we would like to have a group co-owner and/or Moderator present 24/7, that is not possible, as group co-owners and Moderators have a life too. Therefore, there will be times when a group co-owner and/or a moderator will not be present. This will affect the time a moderated member's messages may take to get approved/rejected. This occurs most often during major holidays Also, the group's server is not maintained by the group co-owner(s) or Moderators.

Therefore, when Yahoo has problems affecting Yahoo Groups, ALL members will simply have to wait for Yahoo to fix the problem. Group co-owners and Moderators also do not have any control over how the group's server handles attachments to messages or how message search results are provided.

Page 1

As stated above, this group has a set of policies that all members must agree to and abide by. If any member, new or old, that feels they cannot accept the group's policies, that member is free to terminate their membership at any time without notifying the group co-owners and/or Moderators.

Group's Policies:

1. Profanity of any type, regardless of the word and/or phrase(s) used in a message, is not allowed. This includes the use of abbreviation to improper words, use of symbols to substitute for letters, etc. In short, the use of profanity is NOT ALLOWED, PERIOD!!! The quickest way to get banned from this group is to use profanity!!!

2. Disrespect/Flaming any member regardless of the reason, is not allowed.

3. Taking over a thread by a member that changes the threads original subject and content, is not allowed.

4. Messages that contain as part of the message text, discussions of a member's private life are not allowed. Responses to messages are to pertain to the original message subject.

5. Long discussions that are products of an original messages are not allowed. If there are 2 or 3 members who wish to discuss a subject in more detail and at great lengths should take their discussions off the group and continue their discussions using private email addresses.

6. MESSAGES THAT DO NOT CONTAIN ACCEPTABLE MESSAGE SIGNATURES, WILL BE SUMMARILY REJECTED! It takes less than 5 seconds to ensure your message contains an acceptable message signature. There is no excuse for not adding a message signature to your messages. Political or religious signatures/statements are not permitted.

The following are examples of the ONLY acceptable message signatures:

Licensed Amateur Radio members:

Example:
“73s
John WA1ABC”

Non-licensed members

Example:

73s
Mary

If a member does not wish to include their Amateur Radio call sign in their signature, then simply use their first/given/Christian name ONLY, same as non-licensed members.

Each message signature must be positioned at the bottom of the message text and separated by at least one line.

For example:

Hi John,

Yes capacitor C25 is the right cap you should be checking. For details, review the schematic.

73s
Bill

Screen names such as JLH524 or MWPO125 are not acceptable message signatures. Screen names are acceptable ONLY when used as part of the member's email address.

The member's email address is not an acceptable message signature, regardless whether the member's name appears in the email address or not.

A member's “initials” are not acceptable as a messages signature.

A member may add up to 2 additional lines to their message signature. The additional 2 lines may contain a link to the member's website and a link to the member's Amateur Radio club etc. The addition of 3 or more lines to the message signature, listing the many different clubs the member belongs to, the positions they hold within the respective club(s), their professional position within the company the member works for, and other information is considered excessive and not allowed. The following is an example of an acceptable message signature containing two additional line:

73
Mike-w5rkl
www.w5rkl.com
Yahoo Kenwood TS-520_820_530_830 Moderator (Mike-w5rkl is no longer a Moderator, but used as an example--tnx)

In the past there have been members who state our group policies are too strict. We maintain strict group policies for 2 simple reasons:

1. To maintain good order and discipline in the group.
2. Provide a friendly group where all members are treated equally and an environment free of improper behavior

73
Yahoo Kenwood TS-520_820_530_830 Hybrid Group Co-owners and Moderators.

55235. File - Rules, For Sale or Want to buy Posts

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-08-01 10:03:38 UTC

Topic: 54620 Message: 55235

Rules pertaining to Occasional For Sale and Want to Buy Posts.

Members of the TS-520_820_530_830 Yahoo Group who have been members for at least 30 days may place " for sale" posts no more frequently than two in any 30 day period." Want to buy" posts are permitted immediately upon membership and are limited to 2 in any 30 day period.

For sale posts are limited to the sale of TS-510, 515, 520, 820, 530, 830, and the 599 series twins, as well as Kenwood accessories intended for use with these radios.
Also, group members may post "service equipment" for sale. This may include, but are not limited to: vtvms, various signal generators, and other testing/service equipment. Posts must include: the make and model of the item for sale, as well as an accurate description of its condition, and the asking price.

When the item is sold, please make a short post to that effect.

Replies and discussions regarding these posts must be taken off of this group either by direct e-mail to the seller or as directed by the seller.

Buyers and sellers are on their own. The TS-520_820_530_830 Yahoo Group, its owners, co-owners, moderators, or members other than the seller, hold no responsibility for the accuracy of the posts or the credibility of the seller or buyer.

We do not expect that members of this group will misrepresent, or in any way cheat other members. At the co-owners(s)/moderators discretion, we may choose to ban any member from making further for sale posts, or ban the member from this group entirely if we believe their posts or transactions are not of the utmost integrity.

We ask that those who buy and sell equipment as a main business not post here. We will allow posts from members who occasionally restore and sell equipment/accessories as stated above.

We expect our members to use discretion. If excessive traffic develops as a direct result of these postings, they may have to be discontinued.

Walter Breining, N9WB
Joseph T Stiles, WB7UQU

Larry:

No need to take any IF board readings unless you have no TIF signal (Transmit IF) at the RF board.

If that were the case then measure TIF at IF board at Molex Connector IF-3 Pin 2 and/or at the anode of diode D44. Should see approx 250mv. When it arrives at RF board thru the transmit BPF will be approx 35 to 40mv.

You report that you have 290mv of TIF at the RF board. I assume you are measuring at Molex Conn RF-1 Pin 10. You should see approx 35 to 40mv and not 290mv. This indicates that Transmit Mixer Q1/Q8 are not turned on. More on this later.

You report that you have 130mv of RF at the Drains of Q1/Q8. Better and easier place to measure is at MD which is same as solder lug S on VC-1 air variable capacitor. This is the first of the three ganged Drive capacitors nearest the front panel. Solder lug S is the one with smallest number of plates You should have approx 1.5 to 1.8 rms RF volts at MD.

You report that you have 900mv of RF drive at the Plate of the Driver tube Pin 7. Easier place to measure is at solder lug S of air variable capacitor VC-3 (nearest PA cage). You should see approx 60 to 65 rms rf volts.

Lastly you report that you have 500mv of rf drive at control grids of 6146 final tubes pin 5. You should see approx 45 to 47 rms rf volts here.

What is this telling you? Working back from the Finals you can see:
1. You have no rf drive to control grids of the Final tubes
2. You have no rf drive at output of the Driver tube.
3. You have no rf drive at input of the Driver tube.
4. You have no rf drive at the output of the TX Mixer Q1/Q8
5. You have excessive high level of drive at TIF input to RF board. This may be due to Q1/Q8 not being turned on and/or you are actually reading the VCO signal level back feeding thru the BPF. Need decent O-scope to confirm that.

Suggest that you measure TIF at the IF board at IF-3 Pin 2 to confirm that you have approx 35mv of TIF leaving the IF board. More than likely you do.

Do you have a RF signal generator that will output at least 1 volt? If so, easy to inject substitute RF drive at MD (VC-1 Solder lug S). With minimum of 1 volt at 14.175 injected should see good ALC indication and be able to load the radio.

My guess assuming that you do have TIF signal at input of Q1/Q8 that they are not being turned on. Seldom have failed dual gate mosfets. Do not be tempted to change until troubleshooting confirms they are bad.

In addition to needing the TIF signal this TX Mixer also needs VCO signal as the LO (local oscillator). Confirm that LO is there by measuring VCO level at TP-1 on RF board. Should be approx 1.0 rms RF volts. If you have TIF and VCO to Q1/Q8 Mixer then need to verify have

correct bias voltage at G1/G2 to turn on the Mixer. Measure all the DC voltage in TX mode at Q1/Q8 (Drain, G2, G1, and Source). If dont have correct DC voltages at leads of Q1/Q8 then measure voltages at Molex conn RF-2.

One common problem is dirty relay contacts on aux control relay. This Omron MH4P relay is located on Relay unit board on bottom center of radio. Easy to pull and measure the contact resistance of all the contacts. Should see no resistance higher than your DMM with its leads shorted. If high resistance carefully remove cover and carefully clean all the contacts (dont bend the movable leafs).

Suggest you check this relay first before worrying about Q1/Q8 dc voltages.

Terry K9TW

55238. Hybrid Net Update (July 31, 2016)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-08-01 14:44:19 UTC
From: Mark Gilger
Topic: 55238 Message: 55238

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by me, WB0IQK. There
were 10 stations checking in under very poor band conditions.

We had the following number of radios checking in.

1 running TS-520(x)
2 running TS-530(x)
3 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running TS-515
0 running 599 twins
0 running TS-900

I was running my TS-830s + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
5 stations checking in under very poor band conditions.

We had the following number of radios checking in.

1 running TS-520(x)
0 running TS-530(x)
0 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
1 running 599 twins
0 running TS-900

I was running my TS-520s + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:

Subject: RE: [TS-520_820_530_830] Re: No ALC or Transmit TS-820

Larry:No need to take any IF board readings unless you have no TIF signal (Transmit IF) at the RF board. If that were the case then measure TIF at IF board at Molex Connector IF-3 Pin 2 and/or at the anode of diode D44. Should see approx 250mv. When it arrives at RF board thru the transmit BPF will be approx 35 to 40mv. You report that you have 290mv of TIF at the RF board. I assume you are measuring at Molex Conn RF-1 Pin 10. You should see approx 35 to 40mv and not 290mv. This indicates that Transmit Mixer Q1/Q8 are not turned on. More on this later.You report that you have 130mv of RF at the Drains of Q1/Q8. Better and easier place to measure is at MD which is same as solder lug S on VC-1 air variable capacitor. This is the first of the three ganged Drive capacitors nearest the front panel. Solder lug S is the one with smallest number of plates You should have approx 1.5 to 1.8 rms RF volts at MD. You report that you have 900mv of RF drive at the Plate of the Driver tube Pin 7. Easier place to measure is at solder lug S of air variable capacitor VC-3 (nearest PA cage). You should see approx 60 to 65 rms rf volts. Lastly yo u report that you have 500mv of rf drive at control grids of 6146 final tubes pin 5. You should see approx 45 to 47 rms rf volts here. What is this telling you? Working back from the Finals you can see:1. You have no rf drive to control grids of the Final tubes2. You have no rf drive at output of the Driver tube.3. You have no rf drive at input of the Driver tube.4. You have no rf drive at the output of the TX Mixer Q1/Q85. You have excessive high level of drive at TIF input to RF board. Th is may be due to Q1/Q8 not being turned on and/or you are actually reading the VCO signal level back feeding thru the BPF. Need decent O-scope to confirm that. Suggest that you measure TIF at the IF board at IF-3 Pin 2 to confirm that you have approx 35mv of TIF leaving the IF board. More than likely you do. Do you have a RF signal generator that will output at least 1 volt? If so, easy to inject substitute RF drive at MD (VC-1 Solder lug S). With minimum of 1 volt at 14.175 injected should see good ALC indication and be able to load the radio. My guess assuming that you do have TIF signal at input of Q1/Q8 that they are not being turned on. Seldom have failed dual gate mosfets. Do not be tempted to change until troubleshooting confirms they are bad. In addition to needing the TIF signal this TX Mixer also needs VCO signal as the LO (local oscillator). Confirm that LO is there by measuring VCO level at TP-1 on RF board. Should be approx 1.0 rms RF volts. If you have TIF and VCO to Q1/Q8 Mixer then need to verify have correct bias voltage at G1/G2 to turn on the Mixer. Measure all the DC voltage in TX mode at Q1/Q8 (Drain, G2, G1, and Source). If dont have correct DC voltages at leads of Q1/Q8 then measure

voltages at Molex conn RF-2. One common problem is dirty relay contacts on aux control relay. This Omron MH4P relay is located on Relay unit board on bottom center of radio. Easy to pull and measure the contact resistance of all the contacts. Should see no resistance higher than your DMM with its leads shorted. If high resistance carefully remove cover and carefully clean all the contacts (dont bend the movable leafs).Suggest you check this relay first before worrying about Q1/Q8 dc voltages. Terry K9TW

Larry:

I mispoke. I think I said you should see 250mv of 8.830mhz TIF signal at output of the IF board and that is not correct.

When measuring TIF at the IF board at IF-3 Pin 2 or at anode of D44 you should see approx 35mv to 40 mv of RF. You wont see 250mv unless you get on the Drain of Q1 TIF amp (very easy access on component side of the board).

After the Drain of Q1 the 250mv of TIF signal is stepped down via T5.

Looking at the TX Level Diagram you can see 250mv at Q1 Drain noted on the and you can then see 0.038v or 38mv listed at the RF board at Molex Conn RF-1 Pin 10 which is then coupled thru C1 to T1 to the TX Mixer gate 1s.

So go to IF board and measure TIF at the Drain of Q1 and then measure TIF at D44 and/or Molex Conn IF-3 Pin 2 and report back.

Terry K9TW

Terry Thanks

The previous measurements were made on TUNE mode. Now tested the radio on CW mode and getting 100 watts out on ALL bands except 28.0 MHz.

But 1.5 , 3.5 and 10.0 MHz Receiver sensitivity still low. S meter on Calibrator is still around S3 to S5.

I am little timid about adjusting L41 core for fera of snapping the No. 42 wire accidentally as core travels down.

Will keep you posted.

Hi Bob,
I would suggest you first check AVR board regulated 9VDC supply. This supplies 9V to the main oscillator and control circuits.Connect a voltmeter to terminal 9 on the AVR board and adjust VR1 for a reading of 9V +/- 0.2V.If frequency is jumping or noisy or if there are dead spots then it would indicate that the VFO air variable capacitor rotor shaft wiper contact needs cleaning.The 13.8V connector in the back of the rig is very rich with AC ripple. Not sure whether you can use it for your purpose without adequately smoothing/regulating.

Dave

Since the radio was working perfect before L41 went bad, I am a bit reluctant to touch coil pack alignment. The only change is the new L41, which of course is home wound.

On most bands the S meter peak coincides with ALC peak making me believe that alignment is in order. Because on 20 and 40 the radio is working on expected lines, I am taking baby steps to a full alignment, so as not to destroy all the good work done.

At this stage perhaps I should be adjusting L41 itself, because it may be slightly different than the OEM part. As I can see from schematic that L41 is a 1.5 MHz antenna coil, but it also feeds the other bands perhaps acting as a broadband voltage transformer. As such its adjustment could have an effect on 1.5 to a great extant and and to a lesser extant on other bands. But I am intimidated by the fact that the coil and the former are a bit fragile, after all de-soldering and rewinding it had to go through.

At this point I am concerned with low sensitivity on 1.8 and 3.5 MHz. Transmit on both these bands seems OK. Calibrator signal on 40 and 20 should read S9 but it reads S7. I know its not the S Meter.

My question now is : How can entire coil pack go out of alignment by simply changing a new L41 ? Specially when on all bands the ALC and AGC peaks coincide pretty well.

Rahul,

Rule of thumb, indicates that when you change something you should check to see if it is within specifications. If the readings are out of spec you undertake prescribed alignment. Caps and resistors change their tolerance with age heat etc, this can cause alignment to change.

I base my findings on experience, you may have peak alc readings but that doesn't mean it is still fully aligned to kenwood standards. You should follow the service manual steps when undertaking alignment or checking circuitry. Just tuning one component without looking at all steps may create other problems on other bands.
It is good you are taking baby steps, but don't shot gun problems without following established fault finding and alignment procedures, only my opinion.

Your right to be concerned with ferrite slugs, but there are ways to assist slug removal/loosening if they are tight or stuck.

On my spare rf boards I undertake removal of each wafer switch and solder all the rivers, check for dry joints and cracks throughout the board as preventative rather than cross fingers and hope for the best. Some may say over kill or unnecessary, but wafer switches give problems that are easily overlooked.

We are here to help and offer our experience based.

I have finally got round to replacing the driver and finals including neutralising them in my 830m but there still seems to be a few problems. I have had a good read of the manuals and would appreciate any thoughts from anyone who might have encountered something similar. The cathode resistors all measure around 5ohms. 20m tunes up ok and provides 100w out.
1) when in tune mode and the meter is switched to IP I get no reading on the meter on any bands when in send
2) ALC seems to register fine on all bands apart from 10m - on 10m I can get no ALC reading in tune or cw modes and no RF out. 10m still receives fine and I can hear relay activation when I try to send

Â Hi Mike

Thank you very much for your help. Yes my mistake on the freq change, when I key down on CW as an example the freq display will change from 14.299.0 to 14.299.9 similar to the 800hz you mention. I have only recently started using the radio for CW so its quite likely that I just didn't pick up on this before.
I've had another look this evening and when in TUNE mode there is no IP reading on any band. On 10m in TUNE mode the ALC reading rapidly falls from a low value to near zero and negligable RF power out on CW.

many thanks & 73Laurie G0LTG

On Tuesday, July 12, 2016 8:02 PM, "Mike W5RKL w5rkl@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Â Laurie,

The typical CW transmit frequency "shift" as seen on the digital display is approximately 800Hz which is normal. It's possible you may be reading the digital display incorrectly. Note the CW "receive" frequency indicated on the digital display. Next, key the transmitter in CW mode and note the "transmit" frequency indicated on the digital display. Subtract the transmit digital display frequency from the receive digital display frequency which is the CW transmit "shift" that is occurring.

There will be no transmit frequency "shift" when operating side band.

You say the 830 produces normal 100 watts output on side band on all band, slightly less on 10, that's normal. I am going to assume CW transmit produces the same 100 watts output on all bands, slightly less on 10 meters as well.

You said "there is almost no IP reading in TUNE mode on any band". You then said "IP seems to register normally under CW".

Do you have the meter switch set to ALC in TUNE mode?

Perform the following initial transmitter tuning steps:

1. Set meter switch to ALC
2. Set band switch to say 40 meters
3. Set Mode switch to TUNE
4. Set DRIVE control to 12 o'clock
5. Set CAR control between 10 and 11 o'clock
6. Connect the 830 to your 50 ohm dummy load
7. Power up the 830 and allow it to warmup for 30 minutes
8. Flip the SEND switch UP (Keys transmitter)
9. Adjust the DRIVE control for a peak meter indication, ignoring all meter scale. If the meter pegs fully to the right, rotate the CAR control CCW so the meter drops back to 12 o'clock or so, then continue adjusting the DRIVE control for a peak meter pointer

indication.
10. Once the ALC peak meter pointer indication in TUNE mode is achieves, leave the transmitter keyed for a couple seconds longer while monitoring the meter. If the meter pointer starts to drop back towards zero then the driver tube is weak and should be replaced. If the meter peak remains stable, does not drop back towards zero, then the driver tube can be considered okay. I could be wrong but I suspect, at leas for now, the driver tubes is okay.

This is the initial driver adjustment for maximum RF drive to the final amplifier and a quick way to check the driver tube.

A "dead" driver tube has no control or affect over the final amplifier's 60ma idling current.

A "dead" driver tube has nothing to do with the CW transmit shift seen on the digital display.

A "dead" driver tubes would not produce 100 watts output, as you said, on side band and as I assumed also on CW.

On 7/12/2016 5:30 AM, Laurie J g0ltg@... [TS-520_820_530_830] wrote:

Â Hi All

I was hoping that someone with more experience of the TS-830 might be able to advise me with a few issues that seem to have recently taken place on my TS-830M.

1) There is almost no IP reading when in TUNE mode on any band (IP seems to register normally under CW)2) There is almost no ALC or IP reading on 10m in any mode (and no power output on this band)
3) When in receive and switching from TUNE to CW the frequency counter reading increases by about 5khz.4) When keying down in CW on any band the freq counter reading instantly increases by about 10khz (it drops back again when not transmitting)

I have tried replacing the finals and have the same issues. I have checked that all the switches are in correct positions and tried cleaning them with a dash of deoxit. I have checked the bias and the grid current is set at 60mA. In sideband the radio still provides 100w on all bands apart from 10m and has no frequency shift when transmitting. I am wondering could much or all of this be caused by a dead or dying driver?
many thanks and 73Laurie G0LTG

Hi Bob, if you will go to www.cumbriadesigns.com.uk you will find several examples of how to install one in the Kenwood hybrids. I have installed three units and am very happy!! Two Ten Tec radios and a Tempo one...

Laurie,
Check R11, 470 ohm resistor whilst you have the chance. Remember to check and double check for solder bridges and pinched wires from folding board back.
Glad you've found the problem

I have finally got round to replacing the driver and finals including neutralising them in my 830m but there still seems to be a few problems. I have had a good read of the manuals and would appreciate any thoughts from anyone who might have encountered something similar. The cathode resistors all measure around 5ohms. 20m tunes up ok and provides 100w out.

1) when in tune mode and the meter is switched to IP I get no reading on the meter on any bands when in send

2) ALC seems to register fine on all bands apart from 10m - on 10m I can get no ALC reading in tune or cw modes and no RF out. 10m still receives fine and I can hear relay activation when I try to send

I was a bit vague on my last response.

Repeat the initial TUNE mode DRIVE control transmitter tuning for an ALC meter peak indication but do it on 40 meters. If the peak ALC meter indication in TUNE mode starts to drop back "on its own" toward zero then replace the driver tube.

Hi Mike

Thank you very much for your help. Yes my mistake on the freq change, when I key down on CW as an example the freq display will change from 14.299.0 to 14.299.9 similar to the 800hz you mention. I have only recently started using the radio for CW so its quite likely that I just didn't pick up on this before.

I've had another look this evening and when in TUNE mode there is no IP reading on any band. On 10m in TUNE mode the ALC reading rapidly falls from a low value to near zero and negligable RF power out on CW.

many thanks & 73

Laurie,

The typical CW transmit frequency "shift" as seen on the digital display is approximately 800Hz which is normal. It's possible you may be reading the digital display incorrectly. Note the CW "receive" frequency indicated on the digital display. Next, key the transmitter in CW mode and note the "transmit" frequency indicated on the digital display. Subtract the transmit digital display frequency from the receive digital display frequency which is the CW transmit "shift" that is occurring.

There will be no transmit frequency "shift" when operating side band.

You say the 830 produces normal 100 watts output on side band on all band, slightly less on 10, that's normal. I am going to assume CW transmit produces the same 100 watts output on all bands, slightly less on 10 meters as well.

You said "there is almost no IP reading in TUNE mode on any band". You then said "IP seems to register normally under CW".

Do you have the meter switch set to ALC in TUNE mode?

Perform the following initial transmitter tuning steps:

1. Set meter switch to ALC
2. Set band switch to say 40 meters
3. Set Mode switch to TUNE
4. Set DRIVE control to 12 o'clock
5. Set CAR control between 10 and 11 o'clock
6. Connect the 830 to your 50 ohm dummy load
7. Power up the 830 and allow it to warmup for 30 minutes
8. Flip the SEND switch UP (Keys transmitter)
9. Adjust the DRIVE control for a peak meter indication, ignoring all meter scale. If the meter pegs fully to the right, rotate the CAR control CCW so the meter drops back to 12 o'clock or so, then continue adjusting the DRIVE control for a peak meter pointer indication.
10. Once the ALC peak meter pointer indication in TUNE mode is achieves, leave the transmitter keyed for a couple seconds longer while monitoring the meter. If the meter pointer starts to drop back towards zero then the driver tube is weak and should be replaced. If the meter peak remains stable, does not drop back towards zero, then the driver tube can be considered okay. I could be wrong but I suspect, at leas for now, the driver tubes is okay.

This is the initial driver adjustment for maximum RF drive to the final amplifier and a quick way to check the driver tube.

A "dead" driver tube has no control or affect over the final amplifier's 60ma idling current.

A "dead" driver tube has nothing to do with the CW transmit shift seen on the digital display.

A "dead" driver tubes would not produce 100 watts output, as you said, on side band and as I assumed also on CW.

Â
Hi All

I was hoping that someone with more experience of the TS-830 might be able to advise me with a few issues that seem to have recently taken place on my TS-830M.

1) There is almost no IP reading when in TUNE mode on any band (IP seems to register normally under CW)
2) There is almost no ALC or IP reading on 10m in any mode (and no power output on this band)
3) When in receive and switching from TUNE to CW the frequency counter reading increases by about 5khz.
4) When keying down in CW on any band the freq counter reading instantly increases by about 10khz (it drops back again when not transmitting)

I have tried replacing the finals and have the same issues. I have checked that all the switches are in correct positions and tried cleaning them with a dash of deoxit. I have checked the bias and the grid current is set at 60mA. In sideband the radio still provides 100w on all bands apart from 10m and has no frequency shift when transmitting. I am wondering could much or all of this be caused by a dead or dying driver?

many thanks and 73
Laurie G0LTG

Subject: RE: [TS-520_820_530_830] Re: No ALC or Transmit TS-820

Larry:I mispoke. I think I said you should see 250mv of 8.830mhz TIF signal at output of the IF board and that is not correct. When measuring TIF at the IF board at IF-3 Pin 2 or at anode of D44 you should see approx 35mv to 40 mv of RF. You wont see 250mv unless you get on the Drain of Q1 TIF amp (very easy access on component side of the board). After the Drain of Q1 the 250mv of TIF signal is stepped down via T5. Looking at the TX Level Diagram you can see 250mv at Q1 Drain noted on the and you can then see 0.038v or 38mv l isted at the RF board at Molex Conn RF-1 Pin 10 which is then coupled thru C1 to T1 to the TX Mixer gate 1s. So go to IF board and measure TIF at the Drain of Q1 and then measure TIF at D44 and/or Molex Conn IF-3 Pin 2 and report back. Terry K9TW-In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote :Larry:No need to take any IF board readings unless you have no TIF signal (Transmit IF) at the RF board. If that were the case then measure TI F at IF board at Molex Connector IF-3 Pin 2 and/or at the anode of diode D44. Should see approx 250mv. When it arrives at RF board thru the transmit BPF will be approx 35 to 40mv. You report that you have 290mv of TIF at the RF board. I assume you are measuring at Molex Conn RF-1 Pin 10. You should see approx 35 to 40mv and not 290mv. This indicates that Transmit Mixer Q1/Q8 are not turned on. More on this later.You report that you have 130mv of RF at the Drains of Q1/Q8. Better and easier place to measure is at MD which is same as solder lug S on VC-1 air variable capacitor. This is the first of the three ganged Drive capacitors nearest the front panel. Solder lug S is the one with sm allest number of plates You should have approx 1.5 to 1.8 rms RF volts at MD. You report that you have 900mv of RF drive at the Plate of the Driver tube Pin 7. Easier place to measure is at solder lug S of air variable capacitor VC-3 (nearest PA cage). You should see approx 60 to 65 rms rf volts. Lastly you report that you have 500mv of rf drive at control grids of 6146 final tubes pin 5. You should see approx 45 to 47 rms rf volts here. What is this telling you? Working back from the Finals you can see:1. You have no rf drive to control grids of the Final tubes2. You have no rf drive at output of the Driver tube.3. You have no rf drive at input of the Driver tube.4. You have no rf drive at the output of the TX Mixer Q1/Q85. You have excessive high level of drive at TIF input to RF board. This may be due to Q1/Q8 not being turned on and/or you are actually reading the VCO signal level back feeding thru the BPF. Need decent O-scope to confirm that. Suggest that you measure TIF at the IF board at IF-3 Pin 2 to confirm that you have approx 35mv of TIF leaving the

IF board. More than likely you do. Do you have a RF signal generator that will output at least 1 volt? If so, easy to inject substitute RF drive at MD (VC-1 Solder lug S). With minimum of 1 volt at 14.175 injected should see good ALC indication and be able to load the radio. My guess assuming that you do have TIF signal at input of Q1/Q8 that they are not being turned on. Seldom have failed dual gate mosfets. Do not be tempted to change until troubleshooting confirms they are bad. In addition to needing th e TIF signal this TX Mixer also needs VCO signal as the LO (local oscillator). Confirm that LO is there by measuring VCO level at TP-1 on RF board. Should be approx 1.0 rms RF volts. If you have TIF and VCO to Q1/Q8 Mixer then need to verify have correct bias voltage at G1/G2 to turn on the Mixer. Measure all the DC voltage in TX mode at Q1/Q8 (Drain, G2, G1, and Source). If dont have correct DC voltages at leads of Q1/Q8 then measure voltages at Molex conn RF-2. One common problem is dirty relay contacts on aux control relay. This Omron MH4P relay is located on Relay unit board on bottom center of radio. Easy to pull and measure the contact resistance of all the contacts. Should see no resistance higher than your DMM with its leads shorted. If high resistance carefully remove cover and carefully clean all the contacts (dont bend the movable leafs).Suggest you check this relay first before worrying about Q1/Q8 dc voltages. Terry K9TW

When I began shopping for a second hybrid rig, I had pretty much decided that the TS-530s was the one I wanted. That's the rig I used throughout the 1980s and remembered it fondly.

But when I found a good deal on an 830s with the original box and packing, I went for it. Even though it was in great physical condition, it didn't work quite as well as it ought to. Aligning the coil pack and the IF, yielded a receiver that works like a dream. Still, the transmit was a bit flakey, so I ordered the K4EAA replacement relay, and just to be safe - the screen/cathode resistor kit. Once those were in, the transmitter became 100% solid. It has RCA 6146B finals and gives full output on all bands. I've been using this rig daily on CW and occassionally on SSB and it performs flawlessly.

This may seem odd, but I'd still rather have a TS-530s. So, if anyone is at all interested in a swap, I would love to hear from them. I can provide hi-res pics and can even post videos of my TS-830s in operation.

Tony,
I had the same issue with the receiver going deaf occasionally on my 820S, sometimes responding to a thump on the case. I found a bad solder joint on the (I recall) TIF trace on the front Molex connector on the RF board. Touching up the solder joints on the board cured the problem. Be careful working around these connectors--they can have some pretty good voltage on some of the pins (B+ for the 12BY7A driver, etc).

Topic: 55260 Message: 55262

The TS820S models have common problem with all the Molex Connectors as follows:

1. Connectors may not be fully seated flush on the PC boards with full pin insertion before factory soldering. This is most common on the longer connectors like those found on the IF boards. One end will be fully seated and soldered and the other end is raised up with one or more pins not fully seated and the solder didnt fully wet to the small amount of pin protrusion presented or the small amount of solder has cracked over time around the partially inserted pins.

2. On the end of each Molex connector lead wire is a crimp connector. This connector has a spring temper wedge on its end that slides on the mating pin and makes the contact. Two things are commonly bad that cause difficult intermittent conditions. A. The crimp is poor and does not make good connection to the wire lead conductor. B. The wedge has broken off the end of the crimp connector and is just floating inside the Molex connector body.

The problem is that you can wiggle and or mechanically agitate at a spot and think that the problem is where you are applying that motion and the fault really will be remote from that spot and vibration is just transferring motion to that remote area.

Suggest you start on the RF board using small needle nose pliers and gently pull and press on each lead wire where it enters the Molex Connector body of RF-1 and RF-2. Can do this with the Marker on or with RF injected at SO-239 with a RF Sig Gen.

I would also exercise the RF Attenuator switch when signal is down.

You can measure the resistance of the path from the SO-239 to chassis ground. Insert one ohm meter test prod into the SO-239 and the other touch to chassis. Should read less than 2 ohms if Ant TR relay contacts are good. While reading 2 ohms press the RF attenuator push button and should then read 470 ohms.

I chase these things by injecting test RF and then measure/monitor that RF along the path from the SO-239 to the RF board while I do the lead push/pull described above.

On rare occasions the problem is the Intra Board molex connectors on the RF and Coil Pack boards. Need to unplug RF-1 thru RF-3 and remove Driver Tube and pull the RF board off the Coil Pack board and clean these connectors. Have to unsolder the RF neg feedback and neutralizing lead wires.

Of course problem could be on the IF board and not in the Front End. Can inject test 8.830 RIF at RF board RF-1 to prove that IF board, Product Detector, Audio amp etc are all working and not the source of problem.

Have you pulled both MH4P relays and measured and cleaned the contacts? You said you replaced the relay. Which relay and did you measure its contacts before installing it? Contact resistance should not be any higher than DMM test leads shorted together. Typically 0.1 to 0.2 ohms.

Lynn, I didn't use clock.. I used one from K4DPK. It is very easy to install..no problems. Only one that I had was finding a 12volt supply in radio. My eyes are not very good and can't read the Wiring diagrams very well.. Other than that all ok.. It is fully assembled except hook up in radio..

Great going. Glad you found the 820. I found a beautiful 530S at an estate sale. First hybrid I have ever owned. Just a beauty and so much fun to operate. Good luck in finding one.

>
>
>
> But when I found a good deal on an 830s with the original box and packing, I went for it. Even though it was in great physical condition, it didn't work quite as well as it ought to. Aligning the coil pack and the IF, yielded a receiver that works like a dream. Still, the transmit was a bit flakey, so I ordered the K4EAA replacement relay, and just to be safe - the screen/cathode resistor kit. Once those were in, the transmitter became 100% solid. It has RCA 6146B finals and gives full output on all bands. I've been using this rig daily on CW and occassionally on SSB and it performs flawlessly.

Thank you very much to everyone for suggestions and help. I have replaced R15 and R16 and checked R11 which was fine. I also swapped out the 4 x 470k resistors on the rectifier board that were showing values varying between 500k and 650k.
I now have ALC/IP readings restored on every band (previously there was nothing on 10m) and full output (90-100w) on every band other than 10m where I am getting about 25W. I can live with the 25w on 10m but it would be nice to work out why it is lower than it should be.

Â Hi Mike

Thank you very much for your help. Yes my mistake on the freq change, when I key down on CW as an example the freq display will change from 14.299.0 to 14.299.9 similar to the 800hz you mention. I have only recently started using the radio for CW so its quite likely that I just didn't pick up on this before.
I've had another look this evening and when in TUNE mode there is no IP reading on any band. On 10m in TUNE mode the ALC reading rapidly falls from a low value to near zero and negligable RF power out on CW.

many thanks & 73Laurie G0LTG

On Tuesday, July 12, 2016 8:02 PM, "Mike W5RKL w5rkl@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Â Laurie,

The typical CW transmit frequency "shift" as seen on the digital display is approximately 800Hz which is normal. It's possible you may be reading the digital display incorrectly. Note the CW "receive" frequency indicated on the digital display. Next, key the transmitter in CW mode and note the "transmit" frequency indicated on the digital display. Subtract the transmit digital display frequency from the receive digital display frequency which is the CW transmit "shift" that is occurring.

There will be no transmit frequency "shift" when operating side band.

You say the 830 produces normal 100 watts output on side band on all band, slightly less on 10, that's normal. I am going to assume CW transmit produces the same 100 watts output on all bands, slightly less on 10 meters as well.

You said "there is almost no IP reading in TUNE mode on any band". You then said "IP seems to register normally under CW".

Do you have the meter switch set to ALC in TUNE mode?

Perform the following initial transmitter tuning steps:

1. Set meter switch to ALC
2. Set band switch to say 40 meters

3. Set Mode switch to TUNE
4. Set DRIVE control to 12 o'clock
5. Set CAR control between 10 and 11 o'clock
6. Connect the 830 to your 50 ohm dummy load
7. Power up the 830 and allow it to warmup for 30 minutes
8. Flip the SEND switch UP (Keys transmitter)
9. Adjust the DRIVE control for a peak meter indication, ignoring all meter scale. If the meter pegs fully to the right, rotate the CAR control CCW so the meter drops back to 12 o'clock or so, then continue adjusting the DRIVE control for a peak meter pointer indication.
10. Once the ALC peak meter pointer indication in TUNE mode is achieves, leave the transmitter keyed for a couple seconds longer while monitoring the meter. If the meter pointer starts to drop back towards zero then the driver tube is weak and should be replaced. If the meter peak remains stable, does not drop back towards zero, then the driver tube can be considered okay. I could be wrong but I suspect, at leas for now, the driver tubes is okay.

This is the initial driver adjustment for maximum RF drive to the final amplifier and a quick way to check the driver tube.

A "dead" driver tube has no control or affect over the final amplifier's 60ma idling current.

A "dead" driver tube has nothing to do with the CW transmit shift seen on the digital display.

A "dead" driver tubes would not produce 100 watts output, as you said, on side band and as I assumed also on CW.

Laurie,
You should be getting more output on 10 m. Could be several reasons.
1. Driver tube could be soft and need replacing. Check by tuning on 10m place in 've mode, meter switch to alc, if alc drops towards 0, good sign tube needs replacing.
2 unsure if you have undertaken alignment procedure. This is reasonably simple task but must be careful with ferrite slugs not to Break them. .
3 check wafer switches on rf board may need to be cleaned and or repaired if fingers are loose.

Seeing you do have rf output at 100w on other bands, 10m can be a little fickle when tuning.
Had an 830 on my bench with similar output your seeing. Ended up as soft driver.

Let us know how you go

Hi Dave
Thank you again. I have taken another look today, originally I thought the driver was dying and replaced it with a new one a few weeks ago. However both the old and new seem to have about the same performance levels, I can just about get the ALC to register in the S3 region on 10m but only if i turn the carrier up to full. Otherwise there is no reading at all. It wasnt a band I used often but I do think 10m performed OK before the problem with the IP metering came along.

After checking again there is about 70w on 17m, 30w on 10m and 90-100w on the other bands tested on both a dummy load and antenna with good SWR.

I have gone through the drive coil adjustment and the ALC peak on 10m is still very low (S3). I have not tried the coil pack adjustment yet as I do not have an SSG.
Thanks for the suggestion, I will check the wafer switches on the RF board. Is there a best way to clean them? I'm planning on just using a little deoxit.
I'm now wondering if the NOS driver is not as new as it should be. I don't want to go and buy another and still have the same problem......

Thank you very much to everyone for suggestions and help. I have replaced R15 and R16 and checked R11 which was fine. I also swapped out the 4 x 470k resistors on the rectifier board that were showing values varying between 500k and 650k.
I now have ALC/IP readings restored on every band (previously there was nothing on 10m) and full output (90-100w) on every band other than 10m where I am getting about 25W. I can live with the 25w on 10m but it would be nice to work out why it is lower than it should be.

 I was a bit vague on my last response.

Repeat the initial TUNE mode DRIVE control transmitter tuning for an ALC meter peak indication but do it on 40 meters. If the peak ALC meter indication in TUNE mode starts to drop back "on its own" toward zero then replace the driver tube.

Â Laurie,

The typical CW transmit frequency "shift" as seen on the digital display is approximately 800Hz which is normal. It's possible you may be reading the digital display incorrectly. Note the CW "receive" frequency indicated on the digital display. Next, key the transmitter in CW mode and note the "transmit" frequency indicated on the digital display. Subtract the transmit digital display frequency from the receive digital display frequency which is the CW transmit "shift" that is occurring.

There will be no transmit frequency "shift" when operating side band.

You say the 830 produces normal 100 watts output on side band on all band, slightly less on 10, that's normal. I am going to assume CW transmit produces the same 100 watts output on all bands, slightly less on 10 meters as well.

You said "there is almost no IP reading in TUNE mode on any band". You then said "IP seems to register normally under CW".

Do you have the meter switch set to ALC in TUNE mode?

Perform the following initial transmitter tuning steps:

1. Set meter switch to ALC
2. Set band switch to say 40 meters
3. Set Mode switch to TUNE
4. Set DRIVE control to 12 o'clock
5. Set CAR control between 10 and 11 o'clock
6. Connect the 830 to your 50 ohm dummy load
7. Power up the 830 and allow it to warmup for 30 minutes
8. Flip the SEND switch UP (Keys transmitter)
9. Adjust the DRIVE control for a peak meter indication, ignoring all meter scale. If the meter pegs fully to the right, rotate the CAR control CCW so the meter drops back to 12 o'clock or so, then continue adjusting the DRIVE control for a peak meter pointer indication.
10. Once the ALC peak meter pointer indication in TUNE mode is achieves, leave the transmitter keyed for a couple seconds longer while monitoring the meter. If the meter pointer starts to drop back towards zero then the driver tube is weak and should be replaced. If the meter peak remains stable, does not drop back towards zero, then the driver tube can be considered okay. I could be wrong but I suspect, at leas for now, the driver tubes is okay.

This is the initial driver adjustment for maximum RF drive to the final amplifier and a quick way to check the driver tube.

A "dead" driver tube has no control or affect over the final amplifier's 60ma idling current.

A "dead" driver tube has nothing to do with the CW transmit shift seen on the digital display.

A "dead" driver tubes would not produce 100 watts output, as you said, on side band and as I assumed also on CW.

Â Hi All

I was hoping that someone with more experience of the TS-830 might be able to advise me with a few issues that seem to have recently taken place on my TS-830M.

1) There is almost no IP reading when in TUNE mode on any band (IP seems to register normally under CW)2) There is almost no ALC or IP reading on 10m in any mode (and no power output on this band)
3) When in receive and switching from TUNE to CW the frequency counter reading increases by about 5khz.4) When keying down in CW on any band the freq counter reading instantly

increases by about 10khz (it drops back again when not transmitting)

I have tried replacing the finals and have the same issues. I have checked that all the switches are in correct positions and tried cleaning them with a dash of deoxit. I have checked the bias and the grid current is set at 60mA. In sideband the radio still provides 100w on all bands apart from 10m and has no frequency shift when transmitting. I am wondering could much or all of this be caused by a dead or dying driver?
many thanks and 73Laurie G0LTG

Laurie,
I use an artist small brush and apply a small amount of doxit to each of the wafer switches, the rotate a number of times. Then use canned air to blow dry.
This will only help with grime build up, if the rivets are loose that's a bigger job.

I would do full alignment. If you have club, one if the members may have appropriate ssg.

NOS doesn't mean the tube is 100%. Depends on varying factors, storage position etc.
I rotate all my spare tubes through radios 6 monthly.

Dont give up yet, as your 90% through your problem. I believe once the full alignment has been done you'll find things will be ok.
Have you replaced the hv caps and Rl1 relay?

Hi Dave

Thank you again. I have taken another look today, originally I thought the driver was dying and replaced it with a new one a few weeks ago. However both the old and new seem to have about the same performance levels, I can just about get the ALC to register in the S3 region on 10m but only if i turn the carrier up to full. Otherwise there is no reading at all. It wasnt a band I used often but I do think 10m performed OK before the problem with the IP metering came along.

After checking again there is about 70w on 17m, 30w on 10m and 90-100w on the other bands tested on both a dummy load and antenna with good SWR.

I have gone through the drive coil adjustment and the ALC peak on 10m is still very low (S3). I have not tried the coil pack adjustment yet as I do not have an SSG.

Thanks for the suggestion, I will check the wafer switches on the RF board. Is there a best way to clean them? I'm planning on just using a little deoxit.

I'm now wondering if the NOS driver is not as new as it should be. I don't want to go and buy another and still have the same problem......

Laurie,
You should be getting more output on 10 m. Could be several reasons.
1. Driver tube could be soft and need replacing. Check by tuning on 10m place in 've mode, meter switch to alc, if alc drops towards 0, good sign tube needs replacing.
2 unsure if you have undertaken alignment procedure. This is reasonably simple task but must be careful with ferrite slugs not to Break them. .
3 check wafer switches on rf board may need to be cleaned and or repaired if fingers are loose.

Seeing you do have rf output at 100w on other bands, 10m can be a little fickle when tuning.
Had an 830 on my bench with similar output your seeing. Ended up as soft driver.

Let us know how you go

Laurie,

The typical CW transmit frequency "shift" as seen on the digital display is approximately 800Hz which is normal. It's possible you may be reading the digital display incorrectly. Note the CW "receive" frequency indicated on the digital display. Next, key the transmitter in CW mode and note the "transmit" frequency indicated on the digital display. Subtract the transmit digital display frequency from the receive digital display frequency which is the CW transmit "shift" that is occurring.

There will be no transmit frequency "shift" when operating side band.

You say the 830 produces normal 100 watts output on side band on all band, slightly less on 10, that's normal. I am going to assume CW transmit produces the same 100 watts output on all bands, slightly less on 10 meters as well.

You said "there is almost no IP reading in TUNE mode on any band". You then said "IP seems to register normally under CW".

Do you have the meter switch set to ALC in TUNE mode?

Perform the following initial transmitter tuning steps:

1. Set meter switch to ALC
2. Set band switch to say 40 meters
3. Set Mode switch to TUNE
4. Set DRIVE control to 12 o'clock
5. Set CAR control between 10 and 11 o'clock
6. Connect the 830 to your 50 ohm dummy load
7. Power up the 830 and allow it to warmup for 30 minutes
8. Flip the SEND switch UP (Keys transmitter)
9. Adjust the DRIVE control for a peak meter indication, ignoring all meter scale. If the meter pegs fully to the right, rotate the CAR control CCW so the meter drops back to 12 o'clock or so, then continue adjusting the DRIVE control for a peak meter pointer indication.

10. Once the ALC peak meter pointer indication in TUNE mode is achieves, leave the transmitter keyed for a couple seconds longer while monitoring the meter. If the meter pointer starts to drop back towards zero then the driver tube is weak and should be replaced. If the meter peak remains stable, does not drop back towards zero, then the driver tube can be considered okay. I could be wrong but I suspect, at leas for now, the driver tubes is okay.

This is the initial driver adjustment for maximum RF drive to the final amplifier and a quick way to check the driver tube.

A "dead" driver tube has no control or affect over the final amplifier's 60ma idling current.

A "dead" driver tube has nothing to do with the CW transmit shift seen on the digital display.

A "dead" driver tubes would not produce 100 watts output, as you said, on side band and as I assumed also on CW.

Cliff,

Did you open the DIN plug you have and look at the plug pin's solder side for pin numbers? Quite often you can find the DIN plug pin numbers that correspond to the DIN socket pin numbers by looking at the DIN Plug's solder end of the plug.

Also notice by looking at the DIN socket and how the pins are arranged with GROUND "G" and the remaining pins around the edge of the socket. Using the DIN socket shown on page 25, Fig 5-4, in the 830 manual and an Ohm meter, you should be able to determine which pins to use to connect to the amplifier relay socket. The amp relay socket should be connected to the 830's REMOTE DIN socket pins 2 and 4 which are "N.O." (Normally Open) in Standby (receive).

55273. TS-520S Het Osc problem

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-08-04 17:27:04 UTC
From: jskcs@...
Topic: 55273 Message: 55273

Hello-
New member here with a new TS-520S in the shack where I have an issue with the crystals / RF Board and Het Osc output.

Bandswitch has been thoroughly cleaned..I hook up the Freq. Counter to the Het Osc output of radio and then read RF voltage off of TP3 on the RF Board and I get the following readings

Bandswitch RF Votls Het Osc. freq read
160M 2.968v 10.695
80M 2.787v 12.395
40M 0 0
20M 2.853 22.895
15M 69.3mV 9.965V (should be 29.895)
10M 2.894v 36.895

I have checked crystal continuity to the band switch, with radio off I measure 32.88 k across all the crystals as I turn the bandswitch..reading goes to infinity of course when band switch is turn off that crystal.

I have now put in a new 160M and 40M Het Crystal per the manual and 40M is just dead still..was working a month ago...the crystals have been messed with a tad from previous owners but rig works well on 20M...just need to figure out the 40 me and 15m situation.

Any recommendations are welcome on troubleshooting this and thanks.
John-N2LK

Hi Dave
The rivets look mechanically ok to me and the radio is remarkably clean inside for its age, it has had a dust cover since it was bought new but possibly lack of use over the last 15 years might have contributed to some build up on contacts. I will have a go with some deoxit on a brush over the weekend and see if that makes any difference.

I have recently moved and not a member of a club here but will have an ask around and see if there is someone local with an SSG. If not I might have a trawl of Ebay to see if I can pick one up.
The radio hasn't been touched inside until I opened it up to replace the resistors on the rectifier board and tubes, so it still has the original HV caps and relays. I was planning to replace the caps at some point so I might do that as well over the coming weeks. I had considered getting one of the full recap kits and doing the lot in which case I might hold off on the alignment until that is done. In the mean time I might also see if I can get the loan of a working driver just to double check that the problem is not there.
thanks again for all your help and suggestions

However both the old and new seem to have about the same performance levels, I can just about get the ALC to register in the S3 region on 10m but only if i turn the carrier up to full. Otherwise there is no reading at all. It wasnt a band I used often but I do think 10m performed OK before the problem with

the IP metering came along.

After checking again there is about 70w on 17m, 30w on 10m and 90-100w on the other bands tested on both a dummy load and antenna with good SWR.

I have gone through the drive coil adjustment and the ALC peak on 10m is still very low (S3). I have not tried the coil pack adjustment yet as I do not have an SSG.
Thanks for the suggestion, I will check the wafer switches on the RF board. Is there a best way to clean them? I'm planning on just using a little deoxit.
I'm now wondering if the NOS driver is not as new as it should be. I don't want to go and buy another and still have the same problem......

Â Laurie,

The typical CW transmit frequency "shift" as seen on the digital display is approximately 800Hz which is normal. It's possible you may be reading the digital display incorrectly. Note the CW "receive" frequency indicated on the digital display. Next, key the transmitter in CW mode and note the "transmit" frequency indicated on the digital display. Subtract the transmit digital display frequency from the receive digital display frequency which is the CW transmit "shift" that is occurring.

There will be no transmit frequency "shift" when operating side band.

You say the 830 produces normal 100 watts output on side band on all band, slightly less on 10, that's normal. I am going to assume CW transmit produces the same 100 watts output on all bands, slightly less on 10 meters as well.

You said "there is almost no IP reading in TUNE mode on any band". You then said "IP seems to register normally under CW".

Do you have the meter switch set to ALC in TUNE mode?

Perform the following initial transmitter tuning steps:

1. Set meter switch to ALC
2. Set band switch to say 40 meters
3. Set Mode switch to TUNE
4. Set DRIVE control to 12 o'clock
5. Set CAR control between 10 and 11 o'clock

6. Connect the 830 to your 50 ohm dummy load
7. Power up the 830 and allow it to warmup for 30 minutes
8. Flip the SEND switch UP (Keys transmitter)

9. Adjust the DRIVE control for a peak meter indication, ignoring all meter scale. If the meter pegs fully to the right, rotate the CAR control CCW so the meter drops back to 12 o'clock or so, then continue adjusting the DRIVE control for a peak meter pointer indication.
10. Once the ALC peak meter pointer indication in TUNE mode is achieves, leave the transmitter keyed for a couple seconds longer while monitoring the meter. If the meter pointer starts to drop back towards zero then the driver tube is weak and should be replaced. If the meter peak remains stable, does not drop back towards zero, then the driver tube can be considered okay. I could be wrong but I suspect, at leas for now, the driver tubes is okay.

This is the initial driver adjustment for maximum RF drive to the final amplifier and a quick way to check the driver tube.

A "dead" driver tube has no control or affect over the final amplifier's 60ma idling current.

A "dead" driver tube has nothing to do with the CW transmit shift seen on the digital display.

A "dead" driver tubes would not produce 100 watts output, as you said, on side band and as I assumed also on CW.

55276. Hello and my question

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-08-05 00:35:10 UTC
From: Baruch Atta
Topic: 55276 Message: 55276

First, i would like to say hello to the group. I have had this Kenwood 520s since 1995 and it has worked nicely. It is a bit hairy to tune up though. And that is my question.

I tune up according to the manual using a dummy load. I see on my MFJ Versa Tuner with wattmeter, that the rig is putting out 100 watts and is happy.

then I switch to the antenna, and tune the MFJ tuner to minimum reverse / reflected power, which is minimum SWR. I achieve a 1:1.3 or something llike that.

At this point I switch back to forward power, and see that the power is back down to like 5 watts.

I switch back and forth between tuning the rig and tuning the antenna.

Any advice? This question has probably been asked before, but I can't find it.

thanks
Joe W3TTT

Laurie,
Ok on your observations. The wafer switches should be checked for resistance rather than mechanical. This us achieved removing each wafer board, something I would not recommend without good understanding of the task and without undertaking all other possible issues and undertaking full alignment.
I would recommend neutralizing tubes.
Why would you want to recap the radio when you don't appear to have problems with caps. Shot gunning repairs without proper fault finding techniques. You will end up with more problems I my opinion. I am working offline with another ham who did recap and now has bigger issues, such as not doing each cap and taking out and replacing same way. Some models have the screen printing of polarity backwards on the circuit boards. Not telling you what you can or can't do, just offering friendly advice.
Keep us appraised of your progress

"Laurie J g0ltg@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Hi Dave

The rivets look mechanically ok to me and the radio is remarkably clean inside for its age, it has had a dust cover since it was bought new but possibly lack of use over the last 15 years might have contributed to some build up on contacts. I will have a go with some deoxit on a brush over the weekend and see if that makes any difference.

I have recently moved and not a member of a club here but will have an ask around and see if there is someone local with an SSG. If not I might have a trawl of Ebay to see if I can pick one up.

The radio hasn't been touched inside until I opened it up to replace the resistors on the rectifier board and tubes, so it still has the original HV caps and relays. I was planning to replace the caps at some point so I might do that as well over the coming weeks. I had considered getting one of the full recap kits and doing the lot in which case I might hold off on the alignment until that is done. In the mean time I might also see if I can get the loan of a working driver just to double check that the problem is not there.

thanks again for all your help and suggestions

On Friday, August 5, 2016 1:51 AM, "fpath fpath fpath@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Laurie,

I use an artist small brush and apply a small amount of doxit to each of the wafer switches, the rotate a number of times. Then use canned air to blow dry.
This will only help with grime build up, if the rivets are loose that's a bigger job.

I would do full alignment. If you have club, one if the members may have appropriate ssg.

NOS doesn't mean the tube is 100%. Depends on varying factors, storage position etc.
I rotate all my spare tubes through radios 6 monthly.

Dont give up yet, as your 90% through your problem. I believe once the full alignment has been done you'll find things will be ok.
Have you replaced the hv caps and Rl1 relay?

Subject: RE: [TS-520_820_530_830] Re: No ALC or Transmit TS-820

Larry:I mispoke. I think I said you should see 250mv of 8.830mhz TIF signal at output of the IF board and that is not correct. When measuring TIF at the IF board at IF-3 Pin 2 or at anode of D44 you should see approx 35mv to 40 mv of RF. You wont see 250mv unless you get on the Drain of Q1 TIF amp (very easy access on component side of the board). After the Drain of Q1 the 250mv of TIF signal is stepped down via T5. Looking at the TX Level Diagram you can see 250mv at Q1 Drain noted on the and you can then see 0.038v or 38mv l isted at the RF board at Molex Conn RF-1 Pin 10 which is then coupled thru C1 to T1 to the TX Mixer gate 1s. So go to IF board and measure TIF at the Drain of Q1 and then measure TIF at D44 and/or Molex Conn IF-3 Pin 2 and report back. Terry K9TW-In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote :Larry:No need to take any IF board readings unless you have no TIF signal (Transmit IF) at the RF board. If that were the case then measure TI F at IF board at Molex Connector IF-3 Pin 2 and/or at the anode of diode D44. Should see approx 250mv. When it arrives at RF board thru the transmit BPF will be approx 35 to 40mv. You report that you have 290mv of TIF at the RF board. I assume you are measuring at Molex Conn RF-1 Pin 10. You should see approx 35 to 40mv and not 290mv. This indicates that Transmit Mixer Q1/Q8 are not turned on. More on this later.You report that you have 130mv of RF at the Drains of Q1/Q8. Better and easier place to measure is at MD which is same as solder lug S on VC-1 air variable capacitor. This is the first of the three ganged Drive capacitors nearest the front panel. Solder lug S is the one with sm allest number of plates You should have approx 1.5 to 1.8 rms RF volts at MD. You report that you have 900mv of RF drive at the Plate of the Driver tube Pin 7. Easier place to measure is at solder lug S of air variable capacitor VC-3 (nearest PA cage). You should see approx 60 to 65 rms rf volts. Lastly you report that you have 500mv of rf drive at control grids of 6146 final tubes pin 5. You should see approx 45 to 47 rms rf volts here. What is this telling you? Working back from the Finals you can see:1. You have no rf drive to control grids of the Final tubes2. You have no rf drive at output of the Driver tube.3. You

have no rf drive at input of the Driver tube.4. You have no rf drive at the output of the TX Mixer Q1/Q85. You have excessive high level of drive at TIF input to RF board. This may be due to Q1/Q8 not being turned on and/or you are actually reading the VCO signal level back feeding thru the BPF. Need decent O-scope to confirm that. Suggest that you measure TIF at the IF board at IF-3 Pin 2 to confirm that you have approx 35mv of TIF leaving the IF board. More than likely you do. Do you have a RF signal generator that will output at least 1 volt? If so, easy to inject substitute RF drive at MD (VC-1 Solder lug S). With minimum of 1 volt at 14.175 injected should see good ALC indication and be able to load the radio. My guess assuming that you do have TIF signal at input of Q1/Q8 that they are not being turned on. Seldom have failed dual gate mosfets. Do not be tempted to change until troubleshooting confirms they are bad. In addition to needing th e TIF signal this TX Mixer also needs VCO signal as the LO (local oscillator). Confirm that LO is there by measuring VCO level at TP-1 on RF board. Should be approx 1.0 rms RF volts. If you have TIF and VCO to Q1/Q8 Mixer then need to verify have correct bias voltage at G1/G2 to turn on the Mixer. Measure all the DC voltage in TX mode at Q1/Q8 (Drain, G2, G1, and Source). If dont have correct DC voltages at leads of Q1/Q8 then measure voltages at Molex conn RF-2. One common problem is dirty relay contacts on aux control relay. This Omron MH4P relay is located on Relay unit board on bottom center of radio. Easy to pull and measure the contact resistance of all the contacts. Should see no resistance higher than your DMM with its leads shorted. If high resistance carefully remove cover and carefully clean all the contacts (dont bend the movable leafs).Suggest you check this relay first before worrying about Q1/Q8 dc voltages. Terry K9TW

Hi Dave,I will leave the radio alone for now until I can get it fully aligned, I certainly dont fancy taking out the wafer boards, tomorrow I should get the chance to apply some deoxit with a small brush to see if that has any effect on 10m. The finals have been neutralised already and I'm happy with the output on other bands which all seem to perform well or close to where they should be.

I'm very glad to have the IP metering working again and probably should be spending more time making use of the radio!

  Laurie,
Ok on your observations. The wafer switches should be checked for resistance rather than mechanical. This us achieved removing each wafer board, something I would not recommend without good understanding of the task and without undertaking all other possible issues and undertaking full alignment.
I would recommend neutralizing tubes.
Why would you want to recap the radio when you don't appear to have problems with caps. Shot gunning repairs without proper fault finding techniques. You will end up with more problems I my opinion. I am working offline with another ham who did recap and now has bigger issues, such as not doing each cap and taking out and replacing same way. Some models have the screen printing of polarity backwards on the circuit boards. Not telling you what you can or can't do, just offering friendly advice.
Keep us appraised of your progress

 Hi Dave
The rivets look mechanically ok to me and the radio is remarkably clean inside for its age, it has had a dust cover since it was bought new but possibly lack of use over the last 15 years might have contributed to some build up on contacts. I will have a go with some deoxit on a brush over the weekend and see if that makes any difference.

I have recently moved and not a member of a club here but will have an ask around and see if there is someone local with an SSG. If not I might have a trawl of Ebay to see if I can pick one up.
The radio hasn't been touched inside until I opened it up to replace the resistors on the rectifier board and tubes, so it still has the original HV caps and relays. I was planning to replace the caps at some point so I might do that as well over the coming weeks. I had considered getting one of the full recap kits and doing the lot in which case I might hold off on the alignment until that is done. In the mean time I might also see if I can get the

loan of a working driver just to double check that the problem is not there.
thanks again for all your help and suggestions

Laurie,

I use an artist small brush and apply a small amount of doxit to each of the wafer switches, the rotate a number of times. Then use canned air to blow dry.
This will only help with grime build up, if the rivets are loose that's a bigger job.

I would do full alignment. If you have club, one if the members may have appropriate ssg.

NOS doesn't mean the tube is 100%. Depends on varying factors, storage position etc.
I rotate all my spare tubes through radios 6 monthly.

Dont give up yet, as your 90% through your problem. I believe once the full alignment has been done you'll find things will be ok.
Have you replaced the hv caps and Rl1 relay?

Hi Dave
Thank you again. I have taken another look today, originally I thought the driver was dying and replaced it with a new one a few weeks ago. However both the old and new seem to have about the same performance levels, I can just about get the ALC to register in the S3 region on 10m but only if i turn the carrier up to full. Otherwise there is no reading at all. It wasnt a band I used often but I do think 10m performed OK before the problem with the IP metering came along.

After checking again there is about 70w on 17m, 30w on 10m and 90-100w on the other bands tested on both a dummy load and antenna with good SWR.

I have gone through the drive coil adjustment and the ALC peak on 10m is still very low (S3). I have not tried the coil pack adjustment yet as I do not have an SSG.
Thanks for the suggestion, I will check the wafer switches on the RF board. Is there a best way to clean them? I'm planning on just using a little deoxit.
I'm now wondering if the NOS driver is not as new as it should be. I don't want to go and buy another and still have the same problem......

Laurie,
You should be getting more output on 10 m. Could be several reasons.
1. Driver tube could be soft and need replacing. Check by tuning on 10m place in 've mode,

meter switch to alc, if alc drops towards 0, good sign tube needs replacing.
2 unsure if you have undertaken alignment procedure. This is reasonably simple task but must be careful with ferrite slugs not to Break them. .
3 check wafer switches on rf board may need to be cleaned and or repaired if fingers are loose.

Seeing you do have rf output at 100w on other bands, 10m can be a little fickle when tuning.
Had an 830 on my bench with similar output your seeing. Ended up as soft driver.

Let us know how you go

Â Hi Mike

Thank you very much for your help. Yes my mistake on the freq change, when I key down on CW as an example the freq display will change from 14.299.0 to 14.299.9 similar to the 800hz you mention. I have only recently started using the radio for CW so its quite likely that I just didn't pick up on this before.
I've had another look this evening and when in TUNE mode there is no IP reading on any band. On 10m in TUNE mode the ALC reading rapidly falls from a low value to near zero and negligable RF power out on CW.

many thanks & 73Laurie G0LTG

On Tuesday, July 12, 2016 8:02 PM, "Mike W5RKL w5rkl@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Â Laurie,

The typical CW transmit frequency "shift" as seen on the digital display is approximately 800Hz which is normal. It's possible you may be reading the digital display incorrectly. Note the CW "receive" frequency indicated on the digital display. Next, key the transmitter in CW mode and note the "transmit" frequency indicated on the digital display. Subtract the transmit digital display frequency from the receive digital display frequency which is the CW transmit "shift" that is occurring.

There will be no transmit frequency "shift" when operating side band.

You say the 830 produces normal 100 watts output on side band on all band, slightly less on 10, that's normal. I am going to assume CW transmit produces the same 100 watts output on all bands, slightly less on 10 meters as well.

You said "there is almost no IP reading in TUNE mode on any band". You then said "IP seems to register normally under CW".

Do you have the meter switch set to ALC in TUNE mode?

Perform the following initial transmitter tuning steps:

1. Set meter switch to ALC
2. Set band switch to say 40 meters
3. Set Mode switch to TUNE
4. Set DRIVE control to 12 o'clock
5. Set CAR control between 10 and 11 o'clock
6. Connect the 830 to your 50 ohm dummy load
7. Power up the 830 and allow it to warmup for 30 minutes
8. Flip the SEND switch UP (Keys transmitter)
9. Adjust the DRIVE control for a peak meter indication, ignoring all meter scale. If the meter pegs fully to the right, rotate the CAR control CCW so the meter drops back to 12 o'clock or so, then continue adjusting the DRIVE control for a peak meter pointer indication.
10. Once the ALC peak meter pointer indication in TUNE mode is achieves, leave the transmitter keyed for a couple seconds longer while monitoring the meter. If the meter pointer starts to drop back towards zero then the driver tube is weak and should be replaced. If the meter peak remains stable, does not drop back towards zero, then the driver tube can be considered okay. I could be wrong but I suspect, at leas for now, the driver tubes is okay.

This is the initial driver adjustment for maximum RF drive to the final amplifier and a quick way to check the driver tube.

A "dead" driver tube has no control or affect over the final amplifier's 60ma idling current.

A "dead" driver tube has nothing to do with the CW transmit shift seen on the digital display.

A "dead" driver tubes would not produce 100 watts output, as you said, on side band and as I assumed also on CW.

Â Hi All

I was hoping that someone with more experience of the TS-830 might be able to advise me with a few issues that seem to have recently taken place on my TS-830M.

1) There is almost no IP reading when in TUNE mode on any band (IP seems to register normally under CW)2) There is almost no ALC or IP reading on 10m in any mode (and no power output on this band)
3) When in receive and switching from TUNE to CW the frequency counter reading increases by about 5khz.4) When keying down in CW on any band the freq counter reading instantly increases by about 10khz (it drops back again when not transmitting)

I have tried replacing the finals and have the same issues. I have checked that all the switches are in correct positions and tried cleaning them with a dash of deoxit. I have checked the bias and the grid current is set at 60mA. In sideband the radio still provides 100w on all bands apart from 10m and has no frequency shift when transmitting. I am wondering could much or all of this be caused by a dead or dying driver?
many thanks and 73Laurie G0LTG

Hi Laurie,

With what you're seeing on 10 meters, I would change that driver again. They aren't that expensive. The NOS tube you're using could certainly be weak. With the symptoms you're describing on 10 meters, it really sounds like it might be a bad driver. Why not check the easy things first.
If you already addressed this, then I missed it in your posts. In that case, ...never mind (-:

Good Luck,

Larry:

When you say "RF sniffer" is this a conventional non-amplified signal diode RF probe that you make contact at test points or is it a proximity detector? There are also voltage doubler diode rf probes.

Drain of Q1 TIF amp on IF board should be approx 250mv to 270mv rms RF volts and IF-3 Pin 2 should be approx 40 to 50mv rms RF volts.

If the Molex connectors at IF-3 Pin 2 or at RF-1 Pin 10 at the RF board are bad or dirty and not making contact (you have an open circuit that the TIF signal is looking at) then you could see on the order of 1200mv rms at Drain of Q1 and approx 700rms RF volts at IF-3 Pin 2.

I would carefully remove and clean Molex connectors. Unplug RF-1 and then read continuity from Pin 10 back to Pin 2 on IF-3. IF-3 can remain plugged in. Should see less than 1 ohm.

If you have good low resistance molex contacts and crimps at each end of lead wire then it comes back to Q1/Q8 Mixer dc voltages (not being turned on) and need to look at RF-2 and look at Aux relay contacts. Measuring relay contact resistance and cleaning relay contacts is simple first step.

Topic: 55091 Message: 55285

I forgot to mention that the rf drive voltage levels I am providing you are with the CAR Level Pot wide open for maximum carrier from the Balanced Modulator. I believe that you previously reported that this is how you have been measuring?

Also, anytime when running the TX Level Diagams you encounter RF voltages that are much higher than expected it is telling you that you have an open or a "load" is turned off. For example, common one is looking at the output of the TX Mixer (at MD or S solder lug on VC-1). Should normally see from 1.5v to 2.0v rms rf volts. Not uncommon to see 7v or greater which is telling you that the TX Mixer drains arent seeing the impedance that is normally presented by the control grid of the Driver tube. You can simulate this by pulling the Driver tube and measuring at MD.

So when running TX Level Diagrams to troubleshoot loss of RF drive or low RF drive you can see both lower and higher than normal RF voltage levels at the test points. You have to understand what that is telling you. In this case assuming your measurements are accurate the very high rf voltage is telling you that there is an open in the path to the gates of TX Mixer or the TX Mixer isnt turned on.

It appears there is nothing wrong with the Q1 TIF amp and there is RF drive at output of the IF board and RF drive at input to the RF board (much higher than normal). There is no RF drive at output of TX Mixer. There is no RF drive at control grid of Driver tube.

This assumes that you have reasonably accurate rf voltage measuring test gear that is equivalent to what KW used when they made the measurements and provided them in the Service Manual. They used a high Z RF VTVM with a low capacitance probe. A 11meg VTVM or 10meg DVM and standard signal diode RF probe (usually less than 20pf shunt capacitance) meets this requirement.

Terry K9TW

Hi Kevin,

Thanks for the reply. The original driver seemed to be working fine on 10m and everything was ok before the IP reading suddenly failed and was traced back to one or more resistors that had gone on the rectifier board (with some very kind help from Dave vk5pdl).

I bought another NOS driver and a pair of finals as all the tubes in the set were still original as far as I know. I neutralised the finals but was still getting the same low output on 10m with either the old or new driver. I do agree though that its quite possible the new driver is also not great. I would happily pick up another if I could find one that I was sure had been tested but suspect that a lot of the NOS stock here in the UK is actually just OS and a bit of pot luck is involved.

Subject: RE: [TS-520_820_530_830] Re: No ALC or Transmit TS-820

Larry:When you say "RF sniffer" is this a conventional non-amplified signal diode RF probe that you make contact at test points or is it a proximity detector? There are also voltage doubler diode rf probes. Drain of Q1 TIF amp on IF board should be approx 250mv to 270mv rms RF volts and IF-3 Pin 2 should be approx 40 to 50mv rms RF volts. If the Molex connectors at IF-3 Pin 2 or at RF-1 Pin 10 at the RF board are bad or dirty and not making contact (you have an open circuit that the TIF signal is looking at) then you could see on the order of 1200mv rms at Drain of Q1 and approx 700rms RF volts at IF-3 Pin 2.< /div>I would carefully remove and clean Molex connectors. Unplug RF-1 and then read continuity from Pin 10 back to Pin 2 on IF-3. IF-3 can remain plugged in. Should see less than 1 ohm. If you have good low resistance molex contacts and crimps at each end of lead wire then it comes back to Q1/Q8 Mixer dc voltages (not being turned on) and need to look at RF-2 and

look at Aux relay contacts. Measuring relay contact resistance and cleaning relay contacts is simple first step. Terry K9TW

Larry:

OK not familiar with the Ramsey probe, but my guess is that it may be a voltage doubler probe? I doubt it has any active devices in it that require DC power.

Couple of observations about your dc readings at Q1/Q8 TX Mixer. The operating bias at G1 looks good. I assume it is negative voltage in Rx mode and switches to positive 2.3vdc when you flip to Send.

There are two problems that I see:
1. The VCO which is the LO for the RX and TX Mixer is very low at 390mv. Depending on the band it should range from approx 800mv to 1.2 volts. Around 1 volt is required for good mixing action to produce the actual RF output transmit frequency that you have the VFO set to. VCO mixes with the TIF signal to produce the actual transmit frequency.

You might measure TP-1 on couple of bands in RX and TX modes.

2, The Drain and Source of Q8 should not read approx the same 9vdc. It would appear that Q8 is shorted which is very unusual.

If you are very confident in your DC DSG1G2 readings then it appears you need to change out Q8. I would repeat Q8 DC measurements before changing out Q8.

Hi Laurie

As long as you are happy, full alignment is essential, this should bring 10m up.

All the best

Hi Dave,
I will leave the radio alone for now until I can get it fully aligned, I certainly dont fancy taking out the wafer boards, tomorrow I should get the chance to apply some deoxit with a small brush to see if that has any effect on 10m. The finals have been neutralised already and I'm happy with the output on other bands which all seem to perform well or close to where they should be.

I'm very glad to have the IP metering working again and probably should be spending more time making use of the radio!

Laurie,
Ok on your observations. The wafer switches should be checked for resistance rather than mechanical. This us achieved removing each wafer board, something I would not recommend without good understanding of the task and without undertaking all other possible issues and undertaking full alignment.
I would recommend neutralizing tubes.
Why would you want to recap the radio when you don't appear to have problems with caps. Shot gunning repairs without proper fault finding techniques. You will end up with more problems I my opinion. I am working offline with another ham who did recap and now has bigger issues, such as not doing each cap and taking out and replacing same way. Some models have the screen printing of polarity backwards on the circuit boards. Not telling you what you can or can't do, just offering friendly advice.
Keep us appraised of your progress

"Laurie J g0ltg@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Hi Dave

The rivets look mechanically ok to me and the radio is remarkably clean inside for its age, it has had a dust cover since it was bought new but possibly lack of use over the last 15 years might have contributed to some build up on contacts. I will have a go with some deoxit on a brush over the weekend and see if that makes any difference.

I have recently moved and not a member of a club here but will have an ask around and see if there is someone local with an SSG. If not I might have a trawl of Ebay to see if I can pick one up.

The radio hasn't been touched inside until I opened it up to replace the resistors on the rectifier board and tubes, so it still has the original HV caps and relays. I was planning to replace the caps at some point so I might do that as well over the coming weeks. I had considered getting one of the full recap kits and doing the lot in which case I might hold off on the alignment until that is done. In the mean time I might also see if I can get the loan of a working driver just to double check that the problem is not there.

thanks again for all your help and suggestions

On Friday, August 5, 2016 1:51 AM, "fpath fpath fpath@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Laurie,

I use an artist small brush and apply a small amount of doxit to each of the wafer switches, the rotate a number of times. Then use canned air to blow dry.
This will only help with grime build up, if the rivets are loose that's a bigger job.

I would do full alignment. If you have club, one if the members may have appropriate ssg.

NOS doesn't mean the tube is 100%. Depends on varying factors, storage position etc.
I rotate all my spare tubes through radios 6 monthly.

Dont give up yet, as your 90% through your problem. I believe once the full alignment has been done you'll find things will be ok.
Have you replaced the hv caps and Rl1 relay?

Hi Dave

Thank you again. I have taken another look today, originally I thought the driver was dying and replaced it with a new one a few weeks ago. However both the old and new seem to have about the same performance levels, I can just about get the ALC to register in the S3 region on 10m but only if i turn the carrier up to full. Otherwise there is no reading at all. It wasnt a band I used often but I do think 10m performed OK before the problem with

the IP metering came along.

After checking again there is about 70w on 17m, 30w on 10m and 90-100w on the other bands tested on both a dummy load and antenna with good SWR.

I have gone through the drive coil adjustment and the ALC peak on 10m is still very low (S3). I have not tried the coil pack adjustment yet as I do not have an SSG.

Thanks for the suggestion, I will check the wafer switches on the RF board. Is there a best way to clean them? I'm planning on just using a little deoxit.

I'm now wondering if the NOS driver is not as new as it should be. I don't want to go and buy another and still have the same problem......

Laurie,
You should be getting more output on 10 m. Could be several reasons.
1. Driver tube could be soft and need replacing. Check by tuning on 10m place in 've mode, meter switch to alc, if alc drops towards 0, good sign tube needs replacing.

2 unsure if you have undertaken alignment procedure. This is reasonably simple task but must be careful with ferrite slugs not to Break them. .
3 check wafer switches on rf board may need to be cleaned and or repaired if fingers are loose.

Seeing you do have rf output at 100w on other bands, 10m can be a little fickle when tuning.
Had an 830 on my bench with similar output your seeing. Ended up as soft driver.

Let us know how you go

Thank you very much to everyone for suggestions and help. I have replaced R15 and R16 and checked R11 which was fine. I also swapped out the 4 x 470k resistors on the rectifier board that were showing values varying between 500k and 650k.

I now have ALC/IP readings restored on every band (previously there was nothing on 10m) and full output (90-100w) on every band other than 10m where I am getting about 25W. I can live with the 25w on 10m but it would be nice to work out why it is lower than it should be.

I have finally got round to replacing the driver and finals including neutralising them in my 830m but there still seems to be a few problems. I have had a good read of the manuals and would appreciate any thoughts from anyone who might have encountered something similar. The cathode resistors all measure around 5ohms. 20m tunes up ok and provides 100w out.

1) when in tune mode and the meter is switched to IP I get no reading on the meter on any bands when in send

2) ALC seems to register fine on all bands apart from 10m - on 10m I can get no ALC reading in tune or cw modes and no RF out. 10m still receives fine and I can hear relay activation when I try to send

Hi Mike

Thank you very much for your help. Yes my mistake on the freq change, when I key down on CW as an example the freq display will change from 14.299.0 to 14.299.9 similar to the 800hz you mention. I have only recently started using the radio for CW so its quite likely that I just didn't pick up on this before.

I've had another look this evening and when in TUNE mode there is no IP reading on any band. On 10m in TUNE mode the ALC reading rapidly falls from a low value to near zero and negligable RF power out on CW.

many thanks & 73

Â
Laurie,

The typical CW transmit frequency "shift" as seen on the digital display is approximately 800Hz which is normal. It's possible you may be reading the digital display incorrectly. Note the CW "receive" frequency indicated on the digital display. Next, key the transmitter in CW mode and note the "transmit" frequency indicated on the digital display. Subtract the transmit digital display frequency from the receive digital display frequency which is the CW transmit "shift" that is occurring.

There will be no transmit frequency "shift" when operating side band.

You say the 830 produces normal 100 watts output on side band on all band, slightly less on 10, that's normal. I am going to assume CW transmit produces the same 100 watts output on all bands, slightly less on 10 meters as well.

You said "there is almost no IP reading in TUNE mode on any band". You then said "IP seems to register normally under CW".

Do you have the meter switch set to ALC in TUNE mode?

Perform the following initial transmitter tuning steps:

1. Set meter switch to ALC
2. Set band switch to say 40 meters
3. Set Mode switch to TUNE
4. Set DRIVE control to 12 o'clock
5. Set CAR control between 10 and 11 o'clock
6. Connect the 830 to your 50 ohm dummy load
7. Power up the 830 and allow it to warmup for 30 minutes
8. Flip the SEND switch UP (Keys transmitter)
9. Adjust the DRIVE control for a peak meter indication, ignoring all meter scale. If the meter pegs fully to the right, rotate the CAR control CCW so the meter drops back to 12 o'clock or so, then continue adjusting the DRIVE control for a peak meter pointer indication.
10. Once the ALC peak meter pointer indication in TUNE mode is achieves, leave the transmitter keyed for a couple seconds longer while monitoring the meter. If the meter pointer starts to drop back towards zero then the driver tube is weak and should be replaced. If the meter peak remains stable, does not drop back towards zero, then the driver tube can be considered okay. I could be wrong but I suspect, at leas for now, the driver tubes is okay.

This is the initial driver adjustment for maximum RF drive to the final amplifier and a quick way to check the driver tube.

A "dead" driver tube has no control or affect over the final amplifier's 60ma idling current.

A "dead" driver tube has nothing to do with the CW transmit shift seen on the digital display.

A "dead" driver tubes would not produce 100 watts output, as you said, on side band and as I assumed also on CW.

Â
Hi All

I was hoping that someone with more experience of the TS-830 might be able to advise me with a few issues that seem to have recently taken place on my TS-830M.

1) There is almost no IP reading when in TUNE mode on any band (IP seems to register normally under CW)
2) There is almost no ALC or IP reading on 10m in any mode (and no power output on this band)
3) When in receive and switching from TUNE to CW the frequency counter reading increases by

about 5khz.
4) When keying down in CW on any band the freq counter reading instantly increases by about 10khz (it drops back again when not transmitting)

I have tried replacing the finals and have the same issues. I have checked that all the switches are in correct positions and tried cleaning them with a dash of deoxit. I have checked the bias and the grid current is set at 60mA. In sideband the radio still provides 100w on all bands apart from 10m and has no frequency shift when transmitting. I am wondering could much or all of this be caused by a dead or dying driver?

many thanks and 73
Laurie G0LTG

55292. Hybrid Net Update (August 7, 2016)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-08-07 22:05:51 UTC
From: Mark Gilger
Topic: 55292 Message: 55292

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by me, WB0IQK. There
were 9 stations checking in under very poor band conditions.

We had the following number of radios checking in.

1 running TS-520(x)
1 running TS-530(x)
2 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running TS-515
0 running 599 twins
0 running TS-900

I was running my TS-830s + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
11 stations checking in under very poor band conditions.

We had the following number of radios checking in.

2 running TS-520(x)
0 running TS-530(x)
1 running TS-820(x)
5 running TS-830S
0 running TS-510
0 running TS-511
1 running 599 twins
0 running TS-900

I was running my TS-520s + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 ☐ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins

November 2015, Saturday net total = 66, Sunday total = 46
December 2015, Saturday net total = 55, Sunday total = 73
January 2016, Saturday net total = 129, Sunday total = 81
February 2016, Saturday net total = 98, Sunday total = 72
March 2016, Saturday net total = 74, Sunday total = 35
April 2016, Saturday net total = 101, Sunday total = 57
May 2016, Saturday net total = 51, Sunday total = 32
June 2016, Saturday net total = 39, Sunday total = 46
July 2016, Saturday net total = 52, Sunday total = 54
August 2016, Saturday net total = 9, Sunday total = 11 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

From: darrellswyatt@...
Topic: 55295 Message: 55295

Hi all,
I am new to the group. I was given a 820 by a friend of mine. It has some issues. SOme of which I need help resolving.
issue #
1- digital display was very flakey--that I have repaired
2- receive is way down.---Transmit works fine with +100W out. didn't check all bands.

these are the symptoms
with 25 khz marker on
1- meter shows no signal with agc off
-2 with agc on meter does show signal of approx s2 the meter drops to zero 0 when agc off

checking Q2 on rf board with agc on
g1=+2.2V
g2=+2.58V
D=+12.61v
S-+2.63 V

with agc off, Q2 voltages do not change
0n rf board

voltages to RF board check as follows

-6 is measuring -5.76
+9 is measuring +9
+14 is measuring +12.65
I am kinda stuck here.
Also a question about the schematics.
there are 2 voltages shown for each component for instance on Q2 RF board the G2 shows +2V and under it there's -3.3V. Is the bottom voltage for receive conditions and top voltage for transmit conditions?

thanks for your help in advance. I would like to get this old boat anchor going.

55296. How to get a Heathkit cw filter (type 404-284-1) working inside of a TS-515

continuating...

Next step i checked the circuit diagrams and came to the result, that the Kenwood filter works with ~4k impedance and Heathkit with ~2k. Later i saw, the 2k is printed on the front side of the
Heatkit filter. To double check, if it works, i soldered a 4k from input and output to ground. Together with the 4k of the circuit this should result in a 2k impedance, this is the result:
https://groups.yahoo.com/neo/groups/TS-520_820_530_830/files/my_sharing/cw-filter2.jpg

A bit better, but far away from beeing perfect. Then i remembered, some filter are needing a capacitive burden on each side. So i soldered 2 variable capacitors 10-65pF from each side of the filter to ground. This is, how it looked like:
https://groups.yahoo.com/neo/groups/TS-520_820_530_830/files/my_sharing/cw-filter3.jpg

At least the double humb was symetric. But back to the roots, something has to be wrong with the impedance. I decided, to replace the 4 parts by 2 potentiometer 5k. This way it was possible, to adjust them to the flattest passband:
https://groups.yahoo.com/neo/groups/TS-520_820_530_830/files/my_sharing/cw-filter4.jpg

After finding a flat passband, i removed both potentiometer and measured their resistance -> 1.3k. Together with the original impedance 4k of the TS-515 circuit the impedance over all is very close to 1000 Ohms. Now it looks nice, isn't it? Even the bandwidth measures 400 Hz, as promised. But how to transform the impedance? IMO there are at least two possibilities: a L-match made of an inductor and a capacitor or a rf transformer.

Best regards,
Bernd DF3DL

For Terry K9TW:
Here are more of the things you thought I should check.
On RF board (DC volts)

Q1-
D+2.22v
G1+1.70v
G2+2.34v
S+11.35v
Q8-
D+9.87v
G1+1.92v
G2+2.34v
S+9.05v

TP-1 is .390v
Plug-in relays were changed out during the past year or so. Thanks again for your great help.
Larry

Hello Terry K9TW:Here is what I got on that measurement you wanted me to get back to you on now that I'm back home at the 820 rig (measured with RF sniffer and DMM):Q1 Drain 640 mvIF-3 Pin#2 290 mvMeanwhile, I'll get back to looking at some of the other areas you commented on.Thanks again,LarryAB5AASent from my Samsung Galaxy smartphone.- Original message -From: "wagstw46@yahoo.com [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> Date:08/01/2016 6:50 PM (GMT-06:00) To: TS-520_820_530_830@yahoogroups.com Cc: Subject: RE: [TS-520_820_530_830] Re: No ALC or Transmit TS-820 Larry:I mispoke. I think I said you should see 250mv of 8.830mhz TIF signal at output of the IF board and that is not correct. When measuring TIF at the IF board at IF-3 Pin 2 or at anode of D44 you should see approx 35mv to 40 mv of RF. You wont see 250mv unless you get on the Drain of Q1 TIF amp (very easy access on component side of the board). After the Drain of Q1 the 250mv of TIF signal is stepped down via T5. Looking at the TX Level Diagram you can see 250mv at Q1 Drain noted on the and you can then see 0.038v or 38mv l isted at the RF board at Molex Conn RF-1 Pin 10 which is then coupled thru C1 to T1 to the TX Mixer gate 1s. So go to IF board and measure TIF at the Drain of Q1 and then measure TIF at D44 and/or Molex Conn IF-3 Pin 2 and report back. Terry K9TW-In

TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote :Larry:No need to take any IF board readings unless you have no TIF signal (Transmit IF) at the RF board. If that were the case then measure TI F at IF board at Molex Connector IF-3 Pin 2 and/or at the anode of diode D44. Should see approx 250mv. When it arrives at RF board thru the transmit BPF will be approx 35 to 40mv. You report that you have 290mv of TIF at the RF board. I assume you are measuring at Molex Conn RF-1 Pin 10. You should see approx 35 to 40mv and not 290mv. This indicates that Transmit Mixer Q1/Q8 are not turned on. More on this later.You report that you have 130mv of RF at the Drains of Q1/Q8. Better and easier place to measure is at MD which is same as solder lug S on VC-1 air variable capacitor. This is the first of the three ganged Drive capacitors nearest the front panel. Solder lug S is the one with sm allest number of plates You should have approx 1.5 to 1.8 rms RF volts at MD. You report that you have 900mv of RF drive at the Plate of the Driver tube Pin 7. Easier place to measure is at solder lug S of air variable capacitor VC-3 (nearest PA cage). You should see approx 60 to 65 rms rf volts. Lastly you report that you have 500mv of rf drive at control grids of 6146 final tubes pin 5. You should see approx 45 to 47 rms rf volts here. What is this telling you? Working back from the Finals you can see:1. You have no rf drive to control grids of the Final tubes2. You have no rf drive at output of the Driver tube.3. You have no rf drive at input of the Driver tube.4. You have no rf drive at the output of the TX Mixer Q1/Q85. You have excessive high level of drive at TIF input to RF board. This may be due to Q1/Q8 not being turned on and/or you are actually reading the VCO signal level back feeding thru the BPF. Need decent O-scope to confirm that. Suggest that you measure TIF at the IF board at IF-3 Pin 2 to confirm that you have approx 35mv of TIF leaving the IF board. More than likely you do. Do you have a RF signal generator that will output at least 1 volt? If so, easy to inject substitute RF drive at MD (VC-1 Solder lug S). With minimum of 1 volt at 14.175 injected should see good ALC indication and be able to load the radio. My guess assuming that you do have TIF signal at input of Q1/Q8 that they are not being turned on. Seldom have failed dual gate mosfets. Do not be tempted to change until troubleshooting confirms they are bad. In addition to needing th e TIF signal this TX Mixer also needs VCO signal as the LO (local oscillator). Confirm that LO is there by measuring VCO level at TP-1 on RF board. Should be approx 1.0 rms RF volts. If you have TIF and VCO to Q1/Q8 Mixer then need to verify have correct bias voltage at G1/G2 to turn on the Mixer. Measure all the DC voltage in TX mode at Q1/Q8 (Drain, G2, G1, and Source). If dont have correct DC voltages at leads of Q1/Q8 then measure voltages at Molex conn RF-2. One common problem is dirty relay contacts on aux control relay. This Omron MH4P relay is located on Relay unit board on bottom center of radio. Easy to pull and measure the contact resistance of all the contacts. Should see no resistance higher than your DMM with its leads shorted. If high resistance carefully remove cover and carefully clean all the contacts (dont bend the movable leafs).Suggest you check this relay first before worrying about Q1/Q8 dc voltages. Terry K9TW

Larry:

Not sure what you ordered. Can find NEC brand 3SK41 and sub NTE-222 on Ebay. I would opt for the nos 3SK41.

When you pull the RF board to replace Q8 also pull R13 82k and R14 3.9k resistors and replace them or at least measure them. These are the Driver tube screen grid voltage dividers and 9 out of 10 TS820s that I see these have drifted very high. R13 is commonly open. This results in higher than normal SG voltage to the Driver tube.

Also take the opportunity to clean all 6 of the intra-board molex connectors. Retack the driver tube neutralizing cap (careful not to bridge foils) and the negative feedback lead wires.

It is also a good time to clean the VFO air variable capacitor rotor shaft wiper contact as you will have a clear shot at the access cover plate screws in the shield can.

Are you sure Q1 drain and source are not reversed. I would repeat measurements.

Did you measure contact resistance of the "new" relays when you changed out the relays? You cant just replace them without doing that. Replacements may have had many operational cycles on them. Did you install them in proper locations?

Terry K9TW

Just my thanks to the group in particular and the many sources of information on the venerable TS-5xx and TS8xx radios. There are an impressive number of dedicated users helping to keep the models on the air.

I have just completed my first repair and well into the second unit to cross my workbench. These 2 TS-530S radios have been most enjoyable to return to operational service.

Both had the HV cap C24 failing, so the pair C24 and C22 were replaced, both had C8 in the PA Cage showing definate signs of stress with splits. Both had R7 and R8 out of tolerance. Additionally the second repair had R1-4 well out of tolerance. It also had the X43-1370-00 Rectifier Unit PCB with R15 and R16 needing replaced, but these don't show on the circuit, but are in the parts list of the -02 variant. An interesting anomaly to keep you on your toes. The only part to show severe damage was on the last radio with C9 well toasted, hopefully when replaced, all that circuit should come back to life.

Having only had one Hybrid radio previously (Yaesu FT-101E), I would venture to say if a nice example of the TS-530S came along it would be tempting to add to radio shack bench.

Regards to all
Al

Hi Dave,
Well I feel pretty silly. After replacing the dead resistors on the rectifier board I did not go back to check the idle plate current in SSB. After checking on send with the mic full CCW in USB and meter on IP, it was hardly showing 10mA. I changed this back to 50mA using the rear bias adjuster and now I have output of 100W on all bands with the carrier set to an expected level.
I have noticed though that peaking the drive control for maximum ALC reading in TUNE when tuning up on 10m does not correspond to the peak RX signal for 10m. I.e., tuning to 100W out on 10m results in the band sounding flat (this is only the case on 10m). Turning the drive slightly left brings RX signals back up but drops the power out to around 50W. I'm assuming this is an alignment issue and as soon as I can locate an SSG I will carry out a full alignment.
Thank you again for your help getting this back up and running for me.
best wishes & 73sLaurie G0LTG

 Hi Dave,I will leave the radio alone for now until I can get it fully aligned, I certainly dont fancy taking out the wafer boards, tomorrow I should get the chance to apply some deoxit with a small brush to see if that has any effect on 10m. The finals have been neutralised already and I'm happy with the output on other bands which all seem to perform well or close to where they should be.

I'm very glad to have the IP metering working again and probably should be spending more time making use of the radio!

 Laurie,
Ok on your observations. The wafer switches should be checked for resistance rather than mechanical. This us achieved removing each wafer board, something I would not recommend without good understanding of the task and without undertaking all other possible issues

and undertaking full alignment.
I would recommend neutralizing tubes.
Why would you want to recap the radio when you don't appear to have problems with caps. Shot gunning repairs without proper fault finding techniques. You will end up with more problems I my opinion. I am working offline with another ham who did recap and now has bigger issues, such as not doing each cap and taking out and replacing same way. Some models have the screen printing of polarity backwards on the circuit boards. Not telling you what you can or can't do, just offering friendly advice.
Keep us appraised of your progress

"Laurie J g0ltg@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Hi Dave
The rivets look mechanically ok to me and the radio is remarkably clean inside for its age, it has had a dust cover since it was bought new but possibly lack of use over the last 15 years might have contributed to some build up on contacts. I will have a go with some deoxit on a brush over the weekend and see if that makes any difference.

I have recently moved and not a member of a club here but will have an ask around and see if there is someone local with an SSG. If not I might have a trawl of Ebay to see if I can pick one up.
The radio hasn't been touched inside until I opened it up to replace the resistors on the rectifier board and tubes, so it still has the original HV caps and relays. I was planning to replace the caps at some point so I might do that as well over the coming weeks. I had considered getting one of the full recap kits and doing the lot in which case I might hold off on the alignment until that is done. In the mean time I might also see if I can get the loan of a working driver just to double check that the problem is not there.
thanks again for all your help and suggestions

On Friday, August 5, 2016 1:51 AM, "fpath fpath fpath@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Laurie,

I use an artist small brush and apply a small amount of doxit to each of the wafer switches, the rotate a number of times. Then use canned air to blow dry.
This will only help with grime build up, if the rivets are loose that's a bigger job.

I would do full alignment. If you have club, one if the members may have appropriate ssg.

NOS doesn't mean the tube is 100%. Depends on varying factors, storage position etc.
I rotate all my spare tubes through radios 6 monthly.

Dont give up yet, as your 90% through your problem. I believe once the full alignment has been done you'll find things will be ok.
Have you replaced the hv caps and Rl1 relay?

Hi Dave
Thank you again. I have taken another look today, originally I thought the driver was dying and replaced it with a new one a few weeks ago. However both the old and new seem to have about the same performance levels, I can just about get the ALC to register in the S3 region on 10m but only if i turn the carrier up to full. Otherwise there is no reading at all. It wasnt a band I used often but I do think 10m performed OK before the problem with the IP metering came along.

After checking again there is about 70w on 17m, 30w on 10m and 90-100w on the other bands tested on both a dummy load and antenna with good SWR.

I have gone through the drive coil adjustment and the ALC peak on 10m is still very low (S3). I have not tried the coil pack adjustment yet as I do not have an SSG.
Thanks for the suggestion, I will check the wafer switches on the RF board. Is there a best way to clean them? I'm planning on just using a little deoxit.
I'm now wondering if the NOS driver is not as new as it should be. I don't want to go and buy another and still have the same problem......

Laurie,
You should be getting more output on 10 m. Could be several reasons.
1. Driver tube could be soft and need replacing. Check by tuning on 10m place in 've mode, meter switch to alc, if alc drops towards 0, good sign tube needs replacing.

2 unsure if you have undertaken alignment procedure. This is reasonably simple task but must be careful with ferrite slugs not to Break them. .
3 check wafer switches on rf board may need to be cleaned and or repaired if fingers are loose.

Seeing you do have rf output at 100w on other bands, 10m can be a little fickle when tuning.
Had an 830 on my bench with similar output your seeing. Ended up as soft driver.

Let us know how you go

Thank you very much to everyone for suggestions and help. I have replaced R15 and R16 and checked R11 which was fine. I also swapped out the 4 x 470k resistors on the rectifier

board that were showing values varying between 500k and 650k.
I now have ALC/IP readings restored on every band (previously there was nothing on 10m) and full output (90-100w) on every band other than 10m where I am getting about 25W. I can live with the 25w on 10m but it would be nice to work out why it is lower than it should be.

Â Hi Mike

Thank you very much for your help. Yes my mistake on the freq change, when I key down on CW as an example the freq display will change from 14.299.0 to 14.299.9 similar to the 800hz you mention. I have only recently started using the radio for CW so its quite likely that I just didn't pick up on this before.
I've had another look this evening and when in TUNE mode there is no IP reading on any band. On 10m in TUNE mode the ALC reading rapidly falls from a low value to near zero and negligable RF power out on CW.

many thanks & 73Laurie G0LTG

On Tuesday, July 12, 2016 8:02 PM, "Mike W5RKL w5rkl@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Â Laurie,

The typical CW transmit frequency "shift" as seen on the digital display is approximately 800Hz which is normal. It's possible you may be reading the digital display incorrectly. Note the CW "receive" frequency indicated on the digital display. Next, key the transmitter in CW mode and note the "transmit" frequency indicated on the digital display. Subtract the transmit digital display frequency from the receive digital display frequency which is the CW transmit "shift" that is occurring.

There will be no transmit frequency "shift" when operating side band.

You say the 830 produces normal 100 watts output on side band on all band, slightly less on 10, that's normal. I am going to assume CW transmit produces the same 100 watts output on all bands, slightly less on 10 meters as well.

You said "there is almost no IP reading in TUNE mode on any band". You then said "IP seems to register normally under CW".

Do you have the meter switch set to ALC in TUNE mode?

Perform the following initial transmitter tuning steps:

1. Set meter switch to ALC
2. Set band switch to say 40 meters
3. Set Mode switch to TUNE
4. Set DRIVE control to 12 o'clock
5. Set CAR control between 10 and 11 o'clock
6. Connect the 830 to your 50 ohm dummy load
7. Power up the 830 and allow it to warmup for 30 minutes
8. Flip the SEND switch UP (Keys transmitter)
9. Adjust the DRIVE control for a peak meter indication, ignoring all meter scale. If the meter pegs fully to the right, rotate the CAR control CCW so the meter drops back to 12 o'clock or so, then continue adjusting the DRIVE control for a peak meter pointer indication.
10. Once the ALC peak meter pointer indication in TUNE mode is achieves, leave the transmitter keyed for a couple seconds longer while monitoring the meter. If the meter pointer starts to drop back towards zero then the driver tube is weak and should be replaced. If the meter peak remains stable, does not drop back towards zero, then the driver tube can be considered okay. I could be wrong but I suspect, at leas for now, the driver tubes is okay.

This is the initial driver adjustment for maximum RF drive to the final amplifier and a quick way to check the driver tube.

A "dead" driver tube has no control or affect over the final amplifier's 60ma idling current.

A "dead" driver tube has nothing to do with the CW transmit shift seen on the digital display.

A "dead" driver tubes would not produce 100 watts output, as you said, on side band and as I assumed also on CW.

On 7/12/2016 5:30 AM, Laurie J g0ltg@... [TS-520_820_530_830] wrote:

Â Hi All

I was hoping that someone with more experience of the TS-830 might be able to advise me with a few issues that seem to have recently taken place on my TS-830M.

1) There is almost no IP reading when in TUNE mode on any band (IP seems to register normally under CW)2) There is almost no ALC or IP reading on 10m in any mode (and no power output on this band)
3) When in receive and switching from TUNE to CW the frequency counter reading increases by about 5khz.4) When keying down in CW on any band the freq counter reading instantly increases by about 10khz (it drops back again when not transmitting)

I have tried replacing the finals and have the same issues. I have checked that all the switches are in correct positions and tried cleaning them with a dash of deoxit. I have checked the bias and the grid current is set at 60mA. In sideband the radio still provides 100w on all bands apart from 10m and has no frequency shift when transmitting. I am wondering could much or all of this be caused by a dead or dying driver?
many thanks and 73Laurie G0LTG

55302. VFO-820 Tuning Dial Lamp

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-08-09 12:34:49 UTC
From: n1psx@...
Topic: 55302 Message: 55302

I posted this previously but it does not seem to have made it through...

Does anyone know where to get a replacement lamp for the VFO-820 tuning dial lamp?

Please advise.

Paul

Paul,
You can check for these bulbs at a well stocked hobby supply store.They are 12v @ 50mA and 4mm, or go to hybridrestore"dot"com ork4eaa"dot"com If using them on an 820 series, you'll have to take an X-Acto knife and cut out a bit of the center(the two holes) so the new bulb can pass through. Some members have also used LEDs...I've found them too bright for my liking.

I have used replacement bulbs from the sources already posted. I have also used the 12V 60 mA bulbs from RadioShack and found them acceptable (a bit brighter) in meters and VFO/dial usage.

Larry:Not sure what you ordered. Can find NEC brand 3SK41 and sub NTE-222 on Ebay. I would opt for the nos 3SK41. When you pull the RF board to replace Q8 also pull R13 82k and R14 3.9k resistors and replace them or at least measure them. These are the Driver tube screen grid voltage dividers and 9 out of 10 TS820s that I see these have drifted very high. R13 is commonly open. This results in higher than normal SG voltage to the Driver tube. Also take the opportunity to clean all 6 of the intra-board molex connectors. Retack the driver tube neutralizi ng cap (careful not to bridge foils) and the negative feedback lead wires.It is also a good time to clean the VFO air variable capacitor rotor shaft wiper contact as you will have a clear shot at the access cover plate screws in the shield can.

"Laurie J g0ltg@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Hi Dave,

Well I feel pretty silly. After replacing the dead resistors on the rectifier board I did not go back to check the idle plate current in SSB. After checking on send with the mic full CCW in USB and meter on IP, it was hardly showing 10mA. I changed this back to 50mA using the rear bias adjuster and now I have output of 100W on all bands with the carrier set to an expected level.

I have noticed though that peaking the drive control for maximum ALC reading in TUNE when tuning up on 10m does not correspond to the peak RX signal for 10m. I.e., tuning to 100W out on 10m results in the band sounding flat (this is only the case on 10m). Turning the drive slightly left brings RX signals back up but drops the power out to around 50W. I'm assuming this is an alignment issue and as soon as I can locate an SSG I will carry out a full alignment.

Thank you again for your help getting this back up and running for me.

best wishes & 73s

Hi Dave,
I will leave the radio alone for now until I can get it fully aligned, I certainly dont

fancy taking out the wafer boards, tomorrow I should get the chance to apply some deoxit with a small brush to see if that has any effect on 10m. The finals have been neutralised already and I'm happy with the output on other bands which all seem to perform well or close to where they should be.

I'm very glad to have the IP metering working again and probably should be spending more time making use of the radio!

Laurie,
Ok on your observations. The wafer switches should be checked for resistance rather than mechanical. This us achieved removing each wafer board, something I would not recommend without good understanding of the task and without undertaking all other possible issues and undertaking full alignment.
I would recommend neutralizing tubes.
Why would you want to recap the radio when you don't appear to have problems with caps. Shot gunning repairs without proper fault finding techniques. You will end up with more problems I my opinion. I am working offline with another ham who did recap and now has bigger issues, such as not doing each cap and taking out and replacing same way. Some models have the screen printing of polarity backwards on the circuit boards. Not telling you what you can or can't do, just offering friendly advice.
Keep us appraised of your progress

"Laurie J g0ltg@yahoo.com [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Hi Dave

The rivets look mechanically ok to me and the radio is remarkably clean inside for its age, it has had a dust cover since it was bought new but possibly lack of use over the last 15 years might have contributed to some build up on contacts. I will have a go with some deoxit on a brush over the weekend and see if that makes any difference.

I have recently moved and not a member of a club here but will have an ask around and see if there is someone local with an SSG. If not I might have a trawl of Ebay to see if I can pick one up.

The radio hasn't been touched inside until I opened it up to replace the resistors on the rectifier board and tubes, so it still has the original HV caps and relays. I was planning to replace the caps at some point so I might do that as well over the coming weeks. I had considered getting one of the full recap kits and doing the lot in which case I might hold off on the alignment until that is done. In the mean time I might also see if I can get the loan of a working driver just to double check that the problem is not there.

thanks again for all your help and suggestions

On Friday, August 5, 2016 1:51 AM, "fpath fpath fpath@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Laurie,

I use an artist small brush and apply a small amount of doxit to each of the wafer switches, the rotate a number of times. Then use canned air to blow dry.
This will only help with grime build up, if the rivets are loose that's a bigger job.

I would do full alignment. If you have club, one if the members may have appropriate ssg.

NOS doesn't mean the tube is 100%. Depends on varying factors, storage position etc.
I rotate all my spare tubes through radios 6 monthly.

Dont give up yet, as your 90% through your problem. I believe once the full alignment has been done you'll find things will be ok.
Have you replaced the hv caps and Rl1 relay?

Hi Dave

Thank you again. I have taken another look today, originally I thought the driver was dying and replaced it with a new one a few weeks ago. However both the old and new seem to have about the same performance levels, I can just about get the ALC to register in the S3 region on 10m but only if i turn the carrier up to full. Otherwise there is no reading at all. It wasnt a band I used often but I do think 10m performed OK before the problem with the IP metering came along.

After checking again there is about 70w on 17m, 30w on 10m and 90-100w on the other bands tested on both a dummy load and antenna with good SWR.

I have gone through the drive coil adjustment and the ALC peak on 10m is still very low (S3). I have not tried the coil pack adjustment yet as I do not have an SSG.

Thanks for the suggestion, I will check the wafer switches on the RF board. Is there a best way to clean them? I'm planning on just using a little deoxit.

I'm now wondering if the NOS driver is not as new as it should be. I don't want to go and buy another and still have the same problem......

Laurie,
You should be getting more output on 10 m. Could be several reasons.
1. Driver tube could be soft and need replacing. Check by tuning on 10m place in 've mode, meter switch to alc, if alc drops towards 0, good sign tube needs replacing.

2 unsure if you have undertaken alignment procedure. This is reasonably simple task but must be careful with ferrite slugs not to Break them. .
3 check wafer switches on rf board may need to be cleaned and or repaired if fingers are loose.

Seeing you do have rf output at 100w on other bands, 10m can be a little fickle when tuning.
Had an 830 on my bench with similar output your seeing. Ended up as soft driver.

Let us know how you go

Thank you very much to everyone for suggestions and help. I have replaced R15 and R16 and checked R11 which was fine. I also swapped out the 4 x 470k resistors on the rectifier board that were showing values varying between 500k and 650k.

I now have ALC/IP readings restored on every band (previously there was nothing on 10m) and full output (90-100w) on every band other than 10m where I am getting about 25W. I can live with the 25w on 10m but it would be nice to work out why it is lower than it should be.

I have finally got round to replacing the driver and finals including neutralising them in my 830m but there still seems to be a few problems. I have had a good read of the manuals and would appreciate any thoughts from anyone who might have encountered something similar. The cathode resistors all measure around 5ohms. 20m tunes up ok and provides 100w out.

1) when in tune mode and the meter is switched to IP I get no reading on the meter on any bands when in send

2) ALC seems to register fine on all bands apart from 10m - on 10m I can get no ALC reading in tune or cw modes and no RF out. 10m still receives fine and I can hear relay activation when I try to send

Â
Hi Mike

Thank you very much for your help. Yes my mistake on the freq change, when I key down on CW as an example the freq display will change from 14.299.0 to 14.299.9 similar to the 800hz you mention. I have only recently started using the radio for CW so its quite likely that I just didn't pick up on this before.

I've had another look this evening and when in TUNE mode there is no IP reading on any band. On 10m in TUNE mode the ALC reading rapidly falls from a low value to near zero and negligable RF power out on CW.

many thanks & 73
Laurie G0LTG

On Tuesday, July 12, 2016 8:02 PM, "Mike W5RKL w5rkl@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Â
Laurie,

The typical CW transmit frequency "shift" as seen on the digital display is approximately 800Hz which is normal. It's possible you may be reading the digital display incorrectly. Note the CW "receive" frequency indicated on the digital display. Next, key the transmitter in CW mode and note the "transmit" frequency indicated on the digital display. Subtract the transmit digital display frequency from the receive digital display frequency which is the CW transmit "shift" that is occurring.

There will be no transmit frequency "shift" when operating side band.

You say the 830 produces normal 100 watts output on side band on all band, slightly less on 10, that's normal. I am going to assume CW transmit produces the same 100 watts output on all bands, slightly less on 10 meters as well.

You said "there is almost no IP reading in TUNE mode on any band". You then said "IP seems to register normally under CW".

Do you have the meter switch set to ALC in TUNE mode?

Perform the following initial transmitter tuning steps:

1. Set meter switch to ALC
2. Set band switch to say 40 meters
3. Set Mode switch to TUNE
4. Set DRIVE control to 12 o'clock
5. Set CAR control between 10 and 11 o'clock
6. Connect the 830 to your 50 ohm dummy load
7. Power up the 830 and allow it to warmup for 30 minutes
8. Flip the SEND switch UP (Keys transmitter)
9. Adjust the DRIVE control for a peak meter indication, ignoring all meter scale. If the

meter pegs fully to the right, rotate the CAR control CCW so the meter drops back to 12 o'clock or so, then continue adjusting the DRIVE control for a peak meter pointer indication.
10. Once the ALC peak meter pointer indication in TUNE mode is achieves, leave the transmitter keyed for a couple seconds longer while monitoring the meter. If the meter pointer starts to drop back towards zero then the driver tube is weak and should be replaced. If the meter peak remains stable, does not drop back towards zero, then the driver tube can be considered okay. I could be wrong but I suspect, at leas for now, the driver tubes is okay.

This is the initial driver adjustment for maximum RF drive to the final amplifier and a quick way to check the driver tube.

A "dead" driver tube has no control or affect over the final amplifier's 60ma idling current.

A "dead" driver tube has nothing to do with the CW transmit shift seen on the digital display.

A "dead" driver tubes would not produce 100 watts output, as you said, on side band and as I assumed also on CW.

On 7/12/2016 5:30 AM, Laurie J g0ltg@... [TS-520_820_530_830] wrote:
Â
Hi All

I was hoping that someone with more experience of the TS-830 might be able to advise me with a few issues that seem to have recently taken place on my TS-830M.

1) There is almost no IP reading when in TUNE mode on any band (IP seems to register normally under CW)
2) There is almost no ALC or IP reading on 10m in any mode (and no power output on this band)
3) When in receive and switching from TUNE to CW the frequency counter reading increases by about 5khz.
4) When keying down in CW on any band the freq counter reading instantly increases by about 10khz (it drops back again when not transmitting)

I have tried replacing the finals and have the same issues. I have checked that all the switches are in correct positions and tried cleaning them with a dash of deoxit. I have checked the bias and the grid current is set at 60mA. In sideband the radio still provides 100w on all bands apart from 10m and has no frequency shift when transmitting. I am wondering could much or all of this be caused by a dead or dying driver?

many thanks and 73
Laurie G0LTG

Al:

Pretty common for C8 RF bypass to have split and cracks in the TS530/830 blue ceramic body and in the other KW hybrids with brown or orange body ones to be discolored and/or have a hole blown in it.

Very curious about C9. What symptoms did the radio display with a failed C9? What circuit came back to life when C9 was replaced? I cant imagine C9 being toasted as it only sees uv and ua rf voltage and current. Were you able to determine root cause of failure?

R15, but not R16 should appear on your schematic.

OK Guys.

I decided to align the ANT and MIX Coils of my 530S.

Started with 1.8 MHz L41, which was rewound. As I turned the screw only half turn in, the calibrator signal disappeared. The L41 had gone bust again !

Yesterday I have gone through entire thankless process again, including removing the RF board and rewinding the L41 !

Now Calibrator signal on most bands is S7. Only 10 MHz is still problem on receive. Maybe that's the only band that needs realignment. All bands peak on RX and TX at same spot of Drive Control.

But as of now, L41 has been rewound 4 times and guess that's enough trouble for me. The rig seems to work OK on 40 and 20 and that's what matters to me for time being. I am too poor to risk putting the screwdriver again inside the radio.

Thanks all for your extremely valuable support, specially Terry, K9TW. You guys have been such great help.

Rahul,

Whilst it is frustrating, L41 needs to work properly. Have you considered contacting Walter.Dilley@... to see if he has a damaged or a know good RF board? You could also try Dick W0NTA, he may be able to help.

To conduct the alignment procedure properly you need a SSG, this will allow you to reach the lower levels that is required. These radios aren't for the fainted hearted to work on, but a methodical approach will see you will. I applaud you for undertaking the task you have so far. Your choice but we are here if you need a hand

OK Guys.

I decided to align the ANT and MIX Coils of my 530S.

Started with 1.8 MHz L41, which was rewound. As I turned the screw only half turn in, the calibrator signal disappeared. The L41 had gone bust again !

Yesterday I have gone through entire thankless process again, including removing the RF board and rewinding the L41 !

Now Calibrator signal on most bands is S7. Only 10 MHz is still problem on receive. Maybe that's the only band that needs realignment. All bands peak on RX and TX at same spot of Drive Control.

But as of now, L41 has been rewound 4 times and guess that's enough trouble for me. The rig seems to work OK on 40 and 20 and that's what matters to me for time being. I am too poor to risk putting the screwdriver again inside the radio.

Thanks all for your extremely valuable support, specially Terry, K9TW. You guys have been such great help.

Hi Laurie,

Sorry to butt in again, but just one thing that may be important. You might want to make sure that bias pot on the rear of the radio is working correctly. It may be fine, but you might want to clean it or even just exercise it a few times to make sure it's working smoothly. If it's dirty and jumps around on you, it could spell more troubles.

Really glad you got things working!

Kevin - N2FLP

Hi Terry,

I have just put the Capacitance meter on C9 and it actually reads 139pF, so not toasted, but looks
like it. Dark brown with some of the covering flaking off. So it may not have introduced any fault (yet).
I was going on its appearance. It is mounted very close to C8 not as is usual cuddling up to C10 and C26 which appear OK and read 439pF across them still in circuit.

The original fault was just low output power, so I inspected and began sorting out the obvious usual
suspects on the strength of that. I was expecting a delivery of parts to complete the replacement of
C9, before I start to bring the voltages up on the Variac and look for anything not behaving itself.

I will follow up with any subsequent results as I progress.

Thanks for taking the time to comment

Regards
Al

55313. DK-520 Digital Adapter Kit

Greetings,

My TS-520 came with a DK-520 adapter/interface for the DG-5 digital readout. I removed it from my rig, today, and have, intact, the unit, interface board, cables, instructions, and hardware (less the notched cover for the DC-DC supply). Is there any demand for these?

73,

Jim K4AXF

Al

C9 is not close to C8??

C9 sits between C15 and C10 near VC-1 frame and its ceramic body is almost touching deck S1-2.

It is part of capacitive voltage divider with C10 which is switched in shunt with VC-1 by S1-3 deck. It is Class 1 Temp Coefficient cap and will most likely have to be replaced with a a COG as an N220 would be pretty hard to find today.

Of course C9 being in the front end (gate of Q1 RF amp LC circuits) it would not be a "usual suspect" when troubleshooting low RF RF drive or low RF output.

On rare occasions you might find C29 on RF board a problem and/or C1 on the Final board. KW unlike Yaesu provided C29 as a dc block to prevent driver plate voltage due to dc leakage appearing at the Final control grids and destroying the tubes.

55315. VFO-820 Tuning Dial lamp replacement

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-08-08 10:09:24 UTC
From: n1psx@...
Topic: 55315 Message: 55315

Does anyone have a good source or idea as to finding a replacement lamp for the dial lamp on the VFO-820 external VFO?

The thing looks sort of odd, being seemingly molded into a little white rubber mounting encasement...

Much appreciated.

Paul

Hi Kevin

Thank you for your comments. I think what may have happened was that I adjusted the bias to 50mA before realising the resistors had gone on the rectifier board and did not readjust it after replacing them. I'm assuming that the original bias reading I saw was incorrect before replacing the resistors or that the new resistors altered the reading. Either way the bias seems completely stable now and is rock solid at 50mA every time I check. This is my first tube rig and I have been away from the hobby for 20 years so I'm learning as I go and appreciate everyone's help.

I went through all the bands today checking output and audio and received good reports throughout. The new 6146Bs will tune up to 100w quite happily below 225mA of plate current and everything seems to be back to normal apart from alignment on 10m which I still need to carry out.

I'm going to stick with Dave's advice for now and not tempt fate by touching anything else! I'm very happy to have it back up and runnning!

Topic: 55318 Message: 55318

Because of a number of issues, after something over 50 years, I have decided to pull the big switch on Ham Radio.

I have in my possession a TS-520 with a defunct XMTR. The rig is in really good shape. But, it has the typical "it keeps blowing the 10 ohm cathode resistors in the final" problem common to the breed. I have fixed it a couple of times but now and again they still pop and I really don't want to get into all that again.

So here's the deal: Here's a great "fixer-upper". The receiver is probably the best receiver I have ever owned. It is just that the XMTR requires more attention than I am willing to give it. I have the books and schematics, they're even blown up so you can actually read them. AND IT IS FREE!!!!!!!

So it is available (did I mention that it is free?) to the first person who would like to have it BUT, I live in Pittsburgh, PA and I'm NOT shipping it ANYWHERE! You gotta come get it! Heck, it's free. How much more do you want?

OK, so you feel a little funny about getting a good rig that that for free. If you feel THAT bad about it, you can give me $20 for the pre-cut, already been tested, ready to use 40 meter dipole to go with it. The antenna is made of that really nice, super-flexible stranded wire and has about 100 ft of RG-58 on it.

This is a good deal! Surely there is somebody out there (near Pittsburgh) would would love to have the rig.

Let me know

George,
The ability of the "plate control" to rotate a full 360 is NORMAL. The load and drive control should not. Take off the top cover and the final amplifier cage cover...WITH THE RIG OFF AND DISCONNECTED FROM ANY POWER SOURCE. Observing the plates of the plate control VC in the final cage...see if they are fully meshed when the white pointer is pointing at 9 o'clock...and approx 50% meshed when the pointer is at approx 1 o'clock or pointing at "14"....these are not exact..but pretty close. You may have a slipping shaft/coupler that needs fixed/tightened

On Jul 21, 2016, at 11:20 PM, W5RKL w5rkl@... [TS-520_820_530_830] <TS-520_820_530_830@yahoogroups.com> wrote:

  Bob,
The KW hybrids, whether it's a TS-520 TS-530, TS-820 or TS-830 transmitters are all tuned the same. All of the KW hybrids have the same Class AB1 final amplifier.

Connect the 820 or 830 to your 50 ohm dummy load. To make it easier, pull any CW key plug from the rear panel CW key socket.

Power up the transceiver and allow it to warm up for at least 30 minutes.

1. Set Meter to ALC2. Set the MODE switch to TUNE. This setting reduces the final tube screen voltage by 47%, resulting in less stress on the final tubes.
3. Set the LOAD control fully CCW and the PLATE control so the knob points within the white silk screen on the front panel based on the band switch setting4. Set the DRIVE control to 12 o'clock5. Set the CAR control to 12 o'clock6. Flip SEND switch UP, keys the transmitter.7. Adjust the DRIVE control for a peak meter indication. You do not need to be concerned about exceeding the top of the ALC scale. If the meter pegs fully to the right adjust the CAR control CCW so the meter pointer drops back to 11 o'clock and continue adjusting the DRIVE control for a peak meter indication.8. Set meter switch to IP and adjust the PLATE control for a DIP in IP current (adjust for lowest IP meter indication).9. Flip the SEND switch down (unkeys transmitter) then set MODE switch to CW.10. Set Meter switch to REL PWR.11. Flip SEND switch UP and adjust the LOAD control for a peak meter indication. If meter pegs fully to the right, adjust the rear panel RF VOLT pot (820, 530 830 or the RF voltage on the side panel on the 520 series transceivers) so the meter drops back to 11 or 12 o'clock and continue adjusting the LOAD control for a peak meter indication. Once the LOAD control is adjusted for maximum meter indication, adjust the RF

VOLT pot so the meter points between 1 and 2 o'clock. The REL PWR meter has no scale and it is not watt meter.
12. Set meter switch to IP and, if necessary, adjust the CAR control so the IP meter does not exceed 220ma for the 520 or 820 and 250ma for the 530 or 830.13. Flip the SEND switch DOWN, unkeys the transmitter, you're done!!
If you do not have a 50 ohm dummy load with a power rating at least twice or higher of the transmitter, I highly recommend you purchase one and use it when you tune your transmitters.

Bob,

The KW hybrids, whether it's a TS-520 TS-530, TS-820 or TS-830 transmitters are all tuned the same. All of the KW hybrids have the same Class AB1 final amplifier.

Connect the 820 or 830 to your 50 ohm dummy load. To make it easier, pull any CW key plug from the rear panel CW key socket.

Power up the transceiver and allow it to warm up for at least 30 minutes.

1. Set Meter to ALC
2. Set the MODE switch to TUNE. This setting reduces the final tube screen voltage by 47%, resulting in less stress on the final tubes.
3. Set the LOAD control fully CCW and the PLATE control so the knob points within the white silk screen on the front panel based on the band switch setting
4. Set the DRIVE control to 12 o'clock
5. Set the CAR control to 12 o'clock
6. Flip SEND switch UP, keys the transmitter.
7. Adjust the DRIVE control for a peak meter indication. You do not need to be concerned about exceeding the top of the ALC scale. If the meter pegs fully to the right adjust the CAR control CCW so the meter pointer drops back to 11 o'clock and continue adjusting the DRIVE control for a peak meter indication.
8. Set meter switch to IP and adjust the PLATE control for a DIP in IP current (adjust for lowest IP meter indication).
9. Flip the SEND switch down (unkeys transmitter) then set MODE switch to CW.
10. Set Meter switch to REL PWR.

11. Flip SEND switch UP and adjust the LOAD control for a peak meter indication. If meter pegs fully to the right, adjust the rear panel RF VOLT pot (820, 530 830 or the RF voltage on the side panel on the 520 series transceivers) so the meter drops back to 11 or 12 o'clock and continue adjusting the LOAD control for a peak meter indication. Once the LOAD control is adjusted for maximum meter indication, adjust the RF VOLT pot so the meter points between 1 and 2 o'clock. The REL PWR meter has no scale and it is not watt meter.
12. Set meter switch to IP and, if necessary, adjust the CAR control so the IP meter does not exceed 220ma for the 520 or 820 and 250ma for the 530 or 830.
13. Flip the SEND switch DOWN, unkeys the transmitter, you're done!!

If you do not have a 50 ohm dummy load with a power rating at least twice or higher of the transmitter, I highly recommend you purchase one and use it when you tune your transmitters.

Subject: [TS-520_820_530_830] Another question

Hello Mike,

I was looking at the transmitter tuning for the 820...mode switch, tune, meter/IP, dip the plate
830...mode switch, tune, meter/RF, peak the RF with the plate control

This is confusing to me. I understand dipping the plate, but is peaking the plate in RF the same ?

...or how to source #34 wire from a small filament transformer on the way to rewinding a TS-830 Plate Choke

Reference
https://groups.yahoo.com/neo/groups/TS-520_820_530_830/files/TS820PA.jpg
https://groups.yahoo.com/neo/groups/TS-520_820_530_830/files/TS820PA.jpg
The installed parts were
R6 2Kohms and R10 10K ohms
The schematic shows
R6 2.7K ohms and R10 4.7K ohms

I found this while repairing extensive damage in the PA. Plate choke , Screen and cathode resistors , small choke at the base of the plate choke and one shorted 6146.

I'm wondering what the difference in parts at R6 and R10 means . Did I miss a 820/830/830M variation , update or service bulletin ? Could this have led to inaccurate Ip indication ? I did remove a shorted tube .

Reference
https://groups.yahoo.com/neo/groups/TS-520_820_530_830/conversations/topics/51854
https://groups.yahoo.com/neo/groups/TS-520_820_530_830/conversations/topics/51854

Many thanks to Terry K9TW for the information . It made winding the plate choke much easier .

For now the 830 is up and running smooth , for now .

The toasted C9 I am referring to is in the PA cage switched by S22-2. It is shown in the schematic next to C10 (390 pF) and C26 (22 pF) and is physically located near them, rather than as I
found it, swung round to be close to C8 (maybe they were better friends). I moved it after I had
measured it and the side that faced C8 showed 101 3kV and TDK brand still visible. Not as discolored as the side that faced towards the rear.

Thanks for the input, sorry for any stress caused by not detailing where I was at.

I just have a quick question to the group for anyone that can answer .I am trying to repair my 820 with receive issues. Looking at the schematic there are 2 voltages shown for some objects one over the other. How do you read these? are the top ones for receive and bottom for transmit? Of vise versa ?
thanks n 73

Darrell,
If you look at the upper right of the TS-820(S) schematic in the Service Manual, you will see the info you need. The voltage shown in parenthesis is during "transmission," the voltage NOT in parenthesis is in "receive."

Hi Darrell,

My copy of the 820S circuits has a legend at the
top of the page that indicates voltage measured
during transmit are in brackets (). Looking at
various areas of the circuit (example RF UNIT, V1
pin2) shows 43V for RX and 0V for TX.

Am,
They are the padder caps for 160/80/40m. My first encounter with this problem was a few years ago. I found all three had gone out of tolerance, and didn't provide enough capacitance. One was cracked from heat , was too close to tube and suffered heat damage. Make sure you use type one rf caps, I couldn't find the same hv ratings and had to go higher. Make sure you reinstall replace the fibreglass lead insulation. Also check the caps and choke between the 6146 tubes, if you have lost the padder caps you might find the caps in this area also cracked or burnt out.

OK No stress. Just didnt make any sense.

Yes fixed padders can deteriorate as they are in RF current service and several are not Class 1 as not avavilable so they used Class 2 in lieu with very high wvdc ratings.

Darrell,

I have the High Resolution TS-820 schematic on my website. Click on the following link to download the schematic.

http://w5rkl.com/wp-content/uploads/2014/04/TS-820-hi-res-schematic.pdf

The schematic contains the "DS-1" digital display option shown "installed" and connected.

The schematic also contains the Signal wiring indicators (Solid Black Line), Control Signal wiring indicators (Dash Line), Common Power Source indicators (Solid Red Line), TB, RB, Control Power Source indicators (Dash Red Line), along with both Receive and Transmit voltages. Red voltages in Parenthesis are for Transmit while Red voltages not in Parenthesis are for receive.

Darrell,
Another area you should consider spending time on and that is the TS-820's service manual's "Circuit Description" section where each stage is discussed. Study and pay attention to the "Block Diagram" so you know how the RX and TX signals flow in the TS820.

I also recommend you spend time learning how the TS820's "PLL" works so you know how the RX and TX signals are processed.

Because of a number of issues, after something over 50 years, I have decided to pull the big switch on Ham Radio.

I have in my possession a TS-520 with a defunct XMTR. The rig is in really good shape. But, it has the typical "it keeps blowing the 10 ohm cathode resistors in the final" problem common to the breed. I have fixed it a couple of times but now and again they still pop and I really don't want to get into all that again.

So here's the deal: Here's a great "fixer-upper". The receiver is probably the best receiver I have ever owned. It is just that the XMTR requires more attention than I am willing to give it. I have the books and schematics, they're even blown up so you can actually read them. AND IT IS FREE!!!!!!!

So it is available (did I mention that it is free?) to the first person who would like to have it BUT, I live in Pittsburgh, PA and I'm NOT shipping it ANYWHERE! You gotta come get it! Heck, it's free. How much more do you want?

OK, so you feel a little funny about getting a good rig that that for free. If you feel THAT bad about it, you can give me $20 for the pre-cut, already been tested, ready to use 40 meter dipole to go with it. The antenna is made of that really nice, super-flexible stranded wire and has about 100 ft of RG-58 on it.

This is a good deal! Surely there is somebody out there (near Pittsburgh) would would love to have the rig.

Let me know

carvintom,
It must have been a difficult set of life circumstances that have led to your decision. And your donation of a great rig to someone on this group is very generous. Hope you are able to continue with your interests in some capacity and that you'll keep contributing in some way. 50 years of experience is extremely valuable. JohnWA3JRS

On Wednesday, August 10, 2016 4:32 PM, "carvintom@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

  Because of a number of issues, after something over 50 years, I have decided to pull the big switch on Ham Radio.

I have in my possession a TS-520 with a defunct XMTR. The rig is in really good shape. But, it has the typical "it keeps blowing the 10 ohm cathode resistors in the final" problem common to the breed. I have fixed it a couple of times but now and again they still pop and I really don't want to get into all that again.

So here's the deal: Here's a great "fixer-upper". The receiver is probably the best receiver I have ever owned. It is just that the XMTR requires more attention than I am willing to give it. I have the books and schematics, they're even blown up so you can actually read them. AND IT IS FREE!!!!!!!

So it is available (did I mention that it is free?) to the first person who would like to have it BUT, I live in Pittsburgh, PA and I'm NOT shipping it ANYWHERE! You gotta come get it! Heck, it's free. How much more do you want?

OK, so you feel a little funny about getting a good rig that that for free. If you feel THAT bad about it, you can give me $20 for the pre-cut, already been tested, ready to use 40 meter dipole to go with it. The antenna is made of that really nice, super-flexible stranded wire and has about 100 ft of RG-58 on it.

This is a good deal! Surely there is somebody out there (near Pittsburgh) would would love to have the rig.

A KA9 located near Pittsburgh. You are the first to respond so it is yours

but you gotta pick it up. I'm not packing or shipping it anywhere past my

driveway.

The dipole is available as well per the original e-mail.

Darrell:

Agree you should read the TS820S circuit descriptions.

However, after reading the Circuit descriptions and studying the related block diagrams for the TS820 found in the Service Manual I suggest you go to the groups Files section and download and read TS820S Tech Info 3. It is a better translation and wont leave you scratching your head quite as much.

The only one I have seen go like firecracker is the Plate block/coupling cap at top of the RF Plate choke.

The padder will see same RF voltage that the Tank cap sees. RF voltage across the Tank capacitor at 100 watts output is approx 545 volts rms.

RF current will be shared between the padders and Tank cap same as for parallel resistors only based on Xc values. RF circ current in the Tank is approx 2.8 amps.

Dont try to measure unless you have proper test gear and probes (capacitive voltage divider based).

Hi Folks;

I've been "readin' the mail" for some time now and not posting. I have a TS-520 that I purchased new around 1976. It has seen light to moderate on/off use over the decades. I always managed to fire it up at least twice a year and usually more. When last used around 4 months ago it was operating fine. No major mods. More details are available.

I want to avoid shipping, so if any licensed ham would like to pick it up along with the owner and service manuals I am located about 12 miles southeast of Syracuse, NY.

73,

Garry WA1GWH

Hi Dave,

Thanks for you comments. I have some 100pF 6kV caps to try in there. C26 and C10 seem to be OK. At least not scorched and while still connected in parallel and the band switch not connecting
them to anything else, they measure 412pF.

Yes, C8 is doing the splits, so it will have a 2 or 3 kV replacement. Then I will be close to applying
some increasing levels of odourless gas from the three little holes in the wall!

Cheers
Al

Thanks Terry,

Interesting to contemplate the voltages across the various components in the PA cage.

I found this http://www.qsl.net/i0jx/capacit.html http://www.qsl.net/i0jx/capacit.html to build up some knowledge. It appears
to explain a few interesting things, particularly the capacitor ratings from the codes on them. But I don't find all the codes on too many of them. The weird bit is the size of modern
devices, they hardly look up to the task.

I won't be putting anything in the workings just to see a meter go to full scale. I saw that
being done on radar units in the Air Force. Over the years I have had demonstrations of how electricity is a colorless, odorless gas that burns with a bright flame!

I had the device run up through the Variac this evening and all was good, mitt nicht spitzensparken. Although some clown had put a 20 Amp fuse in the mains fuse-holder.
That made me go back and triple check everything.

Thanks
Al

Gary,
I would be interested.
I am just south of Albany,NY and could drive out.
I have a dead ts-520 that I have not been able to get going for over a year.
Licensed a general since 2009.
If agreeable to you please email me direct tombewick@... and we could
work out the details of when etc...
I could actually some out tomorrow Saturday 8/13.
73,
Tom Bewick,
K2BEW

Gary,
I responded to your offer on the list but thought I would also send you a personal email as well in case you did not see it.
I am interested in the 520, I have one that was my main rig that I killed when I tried to recap it and shorted out the transmit section about a year ago, I replaced a board and a few other components but could not get it to transmit again. Anyway, it is now a parts radio and I have all the extras for it like the matching tuner and speaker and was thinking of getting another one at some point since it was my main base station and favorite radio.
I have a mobile ic-7100 now in the shack for now.
I am near Albany NY and could drive out tomorrow Saturday the 13th or Sunday the 14th in the afternoon, if those days don't work I could work out another day around my work schedule.
I am a general and have been licensed since 2009.
Thanks and 73,
Tom Bewick, K2BEW

Terry and Dave

The major Problem is 1.8 Receive and 28 Transmit. Please see the table below.

Only components changed is L 41 rewound and Q1 3SK73.

Do you think it will benefit from coilpack realignment. ALC and S meter Max coincide on all bands except 30 M. From what remember S Meter was 9+ on lower bands and S 9 on higher bands before L 41 blowup. While it is easy to line up the coil pack, I will touch only if its going to make substantial difference. On this old radio I have a huge possibility of breaking something during aligning process.

28 Mhz power issue could also be weak 12BY7A.

Rahul,
I certainly believe that will help the situation and do understand your resistance. However, if you feel a little resistance when attempting to adjust one of the slugs, here is what I do. I heat my solder iron up, clean the tip, the place top of solder iron on slug and heat up, do heat up too long, then I use my ceramic screwdriver or plastic driver and turn the tight slug. This usually frees it up to allow slug adjustment. If the slugs cracks, remove and turn around as the slugs have slots both ends. If you can't get slug out report back and we can offer some other solutions, don't smash out or drill out until we have exhausted all our options. Only telling you this just in case you have this problem. It happens to all of us.

Rahul:

L41 has nothing to do with Transmitter function. It has nothing to do with RF drive. L41 is the Ant step up transformer. You can cut it out and still have good RF drive on all bands.

Low RF drive and/or low RF Output on 10 meters can be due to:
1. Driver tube that is getting "soft".
2. Mis-adjusted 10 meter (28.5mhz) Mixer and Drive coils on the Coil Pack board.
3. Dirty10 meter band switch contacts on coil pack red/brown vertical boards.
4. Bad 10 meter contacts (lost contact finger pressure).
5. Loose 10 meter contact rivets.
6. Very low VCO LO signal (very rare)

Mixer coils should be adjusted in Rx mode and not Tx mode as some suggest. However, you can adjust in Tx mode when ALC indication is marginal and requires max CAR Level pot advancement. If you do this you need to understand that you are de-tuning the Receiver and sacrificing some gain.

In absence of RF sig gen you can use the Marker on 28.5 mhz and adjust the Ant and Mixer coils and peak the ALC indication with the Drive control set at 1200. Then you can adjust the Driver coil (orange) with Heaters on, SG switch off and peak the ALC indication. To do this turn the Marker back on and peak the ALC by adjusting both the VFO and the Drive Control for max ALC indication (S-meter). Turn off the Marker and do not touch the VFO. Now peak the Drive coil and it should now be adjusted to peak very close to same place as max receiver noise peaks anywhere in the VFO range.

Before adjusting the 28.5 Ant and Mixer coils take bright lite and examine the ferrite core slug rectangular tuning slot. If pieces are broken out of the slot you can try carefully turning CCW and removing the slug and turning it over and installing it with the good slot upward. All the cores have a tuning slot cut in each end. If the core is frozen (doesnt happen often in 530/830 coils) you can apply lite oil with toothpick or artist brush and let it wick down around the threads to act as penetrating lubricant. Most of the 530/830s that I see with cracked/broken rectangular tuning slots is due to using wrong adjustment tool (metal screwdrivers). I commonly must remove cores and reverse them to get good unmolested slot top side.

So leave the entire coil pack alignment alone at this time and try just peaking 28.5 Ant and Mixers in RX and then the Drive control in Tx using the Marker signal.

I have a white paper on my website that tells how to adjust Drive coils so that the max rx gain and max rf drive appear very close to same position of the VFO and the Drive control.

There is a reason why KW in Step 18 of the Service manual tells you to "receive the Marker frequency". It is just not written as clear as it good be. That is why I wrote my paper putting more meat on the bones.

Hi Folks;

I am currently discussing with Tom K2BEW my offer to give away my TS-520 for the price of picking it up.

Will post again when/if Tom comes by for the radio.

73,

Garry

Terry:
The good news is I replaced Q1and Q8 on the RF board and I could tell receive was much improved. The bad news is the ts-820 would only stay on for about 4 minutes then blow a fuse. Once, when I put it in send, plate current started rising rapidly. Not sure what to check next.

Can find NEC brand 3SK41 and sub NTE-222 on Ebay. I would opt for the nos 3SK41. When you pull the RF board to replace Q8 also pull R13 82k and R14 3.9k resistors and replace them or at least measure them. These are the Driver tube screen grid voltage dividers and 9 out of 10 TS820s that I see these have drifted very high. R13 is commonly open. This results in higher than normal SG voltage to the Driver tube. Also take the opportunity to clean all 6 of the intra-board molex connectors. Retack the driver tube neutralizi ng cap (careful not to bridge foils) and the negative feedback lead wires.It is also a good time to clean the VFO air variable capacitor rotor shaft wiper contact as you will have a clear shot at the access cover plate screws in the shield can. Larry:

No disrespect but the radio is technically complex and not easy using this medium to help even very experienced people troubleshoot. Perhaps time to seek some local help?

Q1 and Q8 are TX Mixer and shouldnt affect receive unless they are being biased on in Rx mode. Anytime the TX Mixer and/or Driver tube arent cut off in Rx will grossly affect your receiver.

As to rising Plate current when you flip to Send was this in SSB mode or CW mode? In SSB mode should be able to set the resting plate current to 60ma and it stay where you set it.

Are you telling me that you were in the process of loading the radio and had already peaked the Drive in Tune mode and had just switched the meter selector switch from ALC to IP and was going to dip the plate current and that is when you noticed it starting to rise?

Plate current rising may be due to loss of operating bias on the control grids. Outright loss of bias will almost instantly cause the Final tubes to go into thermal runaway and plates will glow bright orange in matter of seconds and can quickly destroy the tubes. Common for the fuse to blow. If the bias voltage is slowly going down from its cutoff voltage (-110vdc) or operating level (-60vdc) then most common problem can be a dirty bias voltage adjustment pot. In this case I suspect problem is related to work you just performed.

Usually when you have a new problem occur after having performed corrective maintenance about 90% of the time you have induced that new problem and must go back and carefully examine all of your work. This is called rework and never want to have that happen. In this case you pulled the RF board so I would take a hard look at Molex Connectror RF-3 and Pins 9 and 10 as this is path of cutoff and operating bias voltage from the bias voltage adjust pot. Also look at RF-2 connector. Common to have bad molex connector or bad crimp on lead wire or broken spring temper wedge on crimp. Suggest you keep the heaters turned OFF while you measure and monitor the bias voltage while you plug and unplug RF-3 and RF-2 to reseat them and then gently tug on the noted pins lead wires at these connectors in the bias voltage path. You can see the path if you study the schematic.

Do not put heaters back on until you are certain that you have stable bias at Pin 5 of tube socket lugs on the Final board.

Lastly, it is possible that the Finals are damaged. You may want to remove PA cage cover and watch them when you are ready to commence loading. BE CAREFUL 900vdc Present. See any hint of color must quickly shut down. They will continue to glow orange even after down power as the cathode has been heated by the filament and after filament voltage is removed cathode emission doesnt stop instantly.

This is the best I can do for you.

Topic: 55369 Message: 55369

I am cleaning up a 520 converted to 11 m. In order to remove the osc board I need to remove two nuts that can be reached through access holes.

I don't have a nut driver that will fit through the access holes which look to be 8 cm. My question is what size is the nut.

Knowing the nut size I can research precision nut drivers that will fit through the access holes.

From: Lou Blasco
Topic: 55369 Message: 55370

Hi Gary,

I can't help you with the nut size but had to replace the 29MHz band crystal (X8) in my TS520S. As you know it's quite a job to remove the OSC COIL board just to replace the crystal. I decided to try and replace the crystal without removing the board and found a method that seems easier than the one suggested in the service manual.

I removed the metal shield next to the OSC COIL board and disconnected the shaft coupler for the band switch then pulled the shaft forward until I could get to the solder connections on the OSC COIL board. ** Make sure you don't rotate any of the switch wafers** I un-soldered the old crystal and pushed the pins through until the crystal was free of the board.

I cut a small piece of heatshrink to go around the new crystal. Under the heatshrink I stuck a few inches of tinned copper wire that I bent in an "L" shape to allow me to feed the crystal under the band switch and poke it's wires through the board. It took about three minutes to get the new crystal soldered in place. Once the crystal was soldered in place all I had to do was slide the wire out from under the heatshrink and the job was done. The heatshrink remained on the crystal but it's so small you can't even see it under the band switch. I pushed the band switch shaft back in and replaced the shield and the hard work was done.

After a coil pack adjustment the radio is as good as new and I'm really happy with the results.

PSE remember to properly sign your msgs/posts per group policy. That being said;
  You will have to remove the VFO and all the knobs and the four screws that hold the front panel on to get at the nut holding the mode switch. Good time to clean the front panel and knobs with a NON-ABRASIVE cleaner..if not real dirty "windex" works good...or as I do, wash it in warm water and a bit of dish soap...not dishwasher detergent....too alkaline, rinse and let dry. Good time to service the VFO too...you'll need a 5/64" "allen type" wrench for the VFO knob set screw(s) and a 3mm "allen type" for the VFO retaining screws. The VFO usually rubs because the main knob has been hit somehow, pushing it in. I suggest that you remove the knob, spring and washers(pay attention to arrangement) and then see if the main VFO shaft will now turn without a rub...it should turn smoothly and NOT wobble. There is enough length on the main VFO shaft to move the knob/skirt in or out a bit to maybe solve your rubbing problem.

Yes the front panel must be removed to gain access to the nuts securing
the pots and rotary switches.

You can see this by studying page 28 in the TS-830 service manual. I
recommend you do not attempt to service your TS-830 without having the
TS-830 service manual.

If you do not have the TS-830 service manual, you can download it free
at the following link:

http://w5rkl.com/wp-content/uploads/2014/04/TS-830_Service_manual.pdf

I also recommend you download the high resolution TS-830 schematic at
the following link:

http://w5rkl.com/wp-content/uploads/2014/04/TS-830S-excellent-schematic.pdf

Also, please add an acceptable message signature to the end of messages
you post on this group. Thanks.

Garry,

That was very generous of you.

While a man’s private property is his to do with as he chooses, I personally have seen too much great ham gear sit idle in shacks of now inactive hams, collecting dust by the inches, when it could be put to use by other hams who appreciate and would get years of enjoyment.

Hi Folks;

Tom K2BEW picked up my offered TS-520 this morning and will use it in a complete Kenwood station that he has been assembling.

I will be leaving the group and would like to thank everyone for all the useful information I have acquired.

73,

Garry, WA1GWH

I did manage to get an allen wrench in the hole and tighten it up a bit. its pretty firm now. I didnt have to take off the front panel.
Thanks for the help if I need to remove the panel for something else Ill refer to this.

PSE remember to properly sign your msgs/posts per group policy. That being said;
You will have to remove the VFO and all the knobs and the four screws that hold the front panel on to get at the nut holding the mode switch. Good time to clean the front panel and knobs with a NON-ABRASIVE cleaner..if not real dirty "windex" works good...or as I do, wash it in warm water and a bit of dish soap...not dishwasher detergent....too alkaline, rinse and let dry. Good time to service the VFO too...you'll need a 5/64" "allen type" wrench for the VFO knob set screw(s) and a 3mm "allen type" for the VFO retaining screws. The VFO usually rubs because the main knob has been hit somehow, pushing it in. I suggest that you remove the knob, spring and washers(pay attention to arrangement) and then see if the main VFO shaft will now turn without a rub...it should turn smoothly and NOT wobble. There is enough length on the main VFO shaft to move the knob/skirt in or out a bit to maybe solve your rubbing problem.

George,
Interesting, the mode switch knob on the 830S usually does not have a set screw...it is a push on type, with a piece of spring steel for the insert. The Band Switch knob however, does have a set screw...they are the same size and shape...and could have been easily transposed during a prior removal. So it was the knob that was loose...and not the actual shaft nut??

Hi all
I used the Allen wrench to gently spin the nut on the shaft with a prying motion. It seemed to work and I had just enough room to do the job.
No marks were led on the face. The skirt of the mode switch would have covered any ham fisted scratches anyway.

I have both.

The 830 has WARC and cascaded IF filters so you can adjust the effective bandwidth which makes it a more capable rig if you are chasing DX or wanting to work WARC. Finding an external VFO for the 830 requires a preapproved bank loan and the narrow CW filters are virtually unobtanium unless you buy the $170 Inrad option.

The 820s on the other hand looks much better (the 830 has a plastic meter which looks really tacky compared to the 820s). If you are primarily a rag chewer on the HF bands, the 820s is great and certainly more affordable radio.

I also have both rigs as well and would offer the following in addition to Jeff's comments:

-The 830S, in addition to WARC bands, offers additional features including a good notch filter not present on the 820S, variable bandwidth tuning which helps a lot with CW operation and transmit incremental tuning (XIT) in addition to RIT (which the 820S also has), and a CW narrow mode (for use with optional filters). Of all this, the notch filter was most useful to me, as I don't operate CW so the notch filter was most valuable to me

-The 820S is indeed more tank-like (and heavy) in its build quality and the tuning controls for the 820S are silky smooth

-It's a toss up to me which is better looking, beauty being in the eye of the beholder, but I don't mind the look of the 830S at all

-You'll not generally have to worry about the reliability of your digital display with the 830S. Display problems are, unfortunately, fairly common for the 820S. I've had many, many issues with the DG-1 display unit on my 820S and despite hours of work have never gotten it to function correctly

-Yes, it can be hard to find a matching VFO for the 830S, but you actually have three options which may make the search easier. Finding a good-functioning VFO-230, as Jeff says, is tough and they are expensive. But, the analogue VFO-240 will work and are somewhat less rare and you can also use the VFO-120 if you're not concerned too much about it exactly matching the base unit in looks. I bought the (analog) 120 for not much money and it works fine with the 830S (same functionality as the VFO-240)

-The 830S has jacks on the rear with IF outputs that make it easier to hook up a station monitor like the SM-220. You have to do some soldering on the 820S for that to work. The two IF outputs also make it easier to rig a panadapter for use with the 830S.

-The receiver architecture is different between the two rigs. The 820S is single-conversion and the 830S is dual conversion. Both are excellent for this era, but the 820S may be a little quieter.

Both great rigs. 830S prices do seem to be rising, wheras the 820 series are generally less expensive and more available. If you are a CW operator, the 830S may be the way to go.

Wow!! What great feedback and just what I was looking for. I had no idea the VFO for the 830 was a kings ransom, more than enough for me to say I'll pass on the 830 unless one should fall into my lap on the cheap. I was lucky enough to get the 820S cheap, it still has a few issues that I'm working fixing and one of them is the DG-1 display problem other is I'm low on output power.

When I acquired the unit it had a bad band switch coupler a few lamps out and the DG-1 issue. I have the matching VFO, speaker and tuner so far and MC-50 mic.

I am selling my Gold Label TS-830S (YK-88C CW Filter Installed). This rig only has very minor blemishes, none of which are on the front. It was completlely restored by W0NTA / Dick in 2015 and works as it should. I am selling it with a matching SP-230 Speaker (A/B switch & radio filtering) plus an MC-50 Microphone. These two items are in good condition, work as they should, but did not come from W0NTA. I purchased them on QTH.Com. A very nice, clean owners manual is included. Price is $600 (firm) plus actual shipping (professionally packed and insured) from 62711 (CONUS only please). Listing here first before putting it on QTH.Com next week. Please respond off list and thanks for the bandwidth! / Woody / WD9F / fghester@yahoo.com (I can send pictures to serious buyers).

Keep working on the display. You will get there. My 820s display was intermittent after sitting in a guy’s closet for 20 years. It took a couple of times through the contacts cleaning process before it stabilized but I have not had to mess with it in the 5+ years since. There is good stuff in the archives and on some of the hybrid sites specific on what to check.

Wow!! What great feedback and just what I was looking for. I had no idea the VFO for the 830 was a kings ransom, more than enough for me to say I'll pass on the 830 unless one should fall into my lap on the cheap. I was lucky enough to get the 820S cheap, it still has a few issues that I'm working fixing and one of them is the DG-1 display problem other is I'm low on output power.

When I acquired the unit it had a bad band switch coupler a few lamps out and the DG-1 issue. I have the matching VFO, speaker and tuner so far and MC-50 mic.

I also have both rigs as well and would offer the following in addition to Jeff’s comments:

-The 830S, in addition to WARC bands, offers additional features including a good notch filter not present on the 820S, variable bandwidth tuning which helps a lot with CW operation and transmit incremental tuning (XIT) in addition to RIT (which the 820S also has), and a CW narrow mode (for use with optional filters). Of all this, the notch filter was most useful to me, as I don’t operate CW so the notch filter was most valuable to me

-The 820S is indeed more tank-like (and heavy) in its build quality and the tuning controls for the 820S are silky smooth

-It’s a toss up to me which is better looking, beauty being in the eye of the beholder, but I don’t mind the look of the 830S at all

-You’ll not generally have to worry about the reliability of your digital display with the 830S. Display problems are, unfortunately, fairly common for the 820S. I’ve had many, many issues with the DG-1 display unit on my 820S and despite hours of work have never gotten it to function correctly

-Yes, it can be hard to find a matching VFO for the 830S, but you actually have three options which may make the search easier. Finding a good-functioning VFO-230, as Jeff says, is tough and they are expensive. But, the analogue VFO-240 will work and are somewhat less rare and you can also use the VFO-120 if you’re not concerned too much about it exactly matching the base unit in looks. I bought the (analog) 120 for not much money and it works fine with the 830S (same functionality as the VFO-240)

-The 830S has jacks on the rear with IF outputs that make it easier to hook up a station monitor like the SM-220. You have to do some soldering on the 820S for that to work. The two IF outputs also make it easier to rig a panadapter for use with the 830S.

-The receiver architecture is different between the two rigs. The 820S is single-conversion and the 830S is dual conversion. Both are excellent for this era, but the 820S may be a little quieter.

Both great rigs. 830S prices do seem to be rising, wheras the 820 series are generally less expensive and more available. If you are a CW operator, the 830S may be the way to go.

Subject: Re: [TS-520_820_530_830] Pro's and con's 820S vs 830

I have both.

The 830 has WARC and cascaded IF filters so you can adjust the effective bandwidth which makes it a more capable rig if you are chasing DX or wanting to work WARC. Finding an external VFO for the 830 requires a preapproved bank loan and the narrow CW filters are virtually unobtanium unless you buy the $170 Inrad option.

The 820s on the other hand looks much better (the 830 has a plastic meter which looks really tacky compared to the 820s). If you are primarily a rag chewer on the HF bands, the 820s is great and certainly more affordable radio.

Subject: [TS-520_820_530_830] Pro's and con's 820S vs 830

So here I am with a almost full TS-820S line and was wondering of those that own both lines what are the pros and cons.

I'm thinking about investing in an 830 line before they become too high priced for my budget, whether or not I keep the 820 I'm on the fence.

Cheers

Terry K9TW:
It works! Thought you might want to know the TS-820S you were advising me on now works. You were right on each thing: Indeed, Q8 on the RF board was shorted internally. The reason the rig wasn' t working after that was a reconstruct error on my part. I cleaned the bias pot and the molex connectors and then checked pins 9 and 10 on RF 3. When I moved the RF board the bias voltage came back. I had attached the clamp that held the rf board to the final housing wrong. It was shorting pin 10 on RF3 to ground. Hope I have reported this correctly. Anyway, thanks again for your advice. Hope this thing keeps working. It's putting out 100 watts on 20 and 80 on 40. I also thank the Lord for his help.

Subject: RE: [TS-520_820_530_830] Re: No ALC or Transmit TS-820

Larry:No disrespect but the radio is technically complex and not easy using this medium to help even very experienced people troubleshoot. Perhaps time to seek some local help? Q1 and Q8 are TX Mixer and shouldnt affect receive unless they are being biased on in Rx mode. Anytime the TX Mixer and/or Driver tube arent cut off in Rx will grossly affect your receiver. As to rising Plate current when you flip to Send was this in SSB mode or CW mode? In SSB mode should be able to set the resting plate current to 60ma and it stay where you set it. Are you telling me that you were in the process of loading the radio and had already peaked the Drive in Tune mode and had just switched the meter selector switch from ALC to IP and was going to dip the plate current and that is when you noticed it starting to rise? Plate current rising may be due to loss of operating bias on the control grids. Outright loss of bias will almost instantly cause the Final tubes to go into thermal runaway and plates will glow bright orange in matter of seconds and can quickly destroy the tubes. Common for the fuse to blow. If the bias voltage is slowly going down from its cutoff voltage (-110vdc) or operating level (-60vdc) then most common problem can be a dirty bias voltage adjustment pot. In this case I suspect problem is related to work you just performed. < /span>Usually when you have a new problem occur after having performed corrective maintenance about 90% of the time you have induced that new problem and must go back and carefully examine all of your work. This is called rework and never want to have that happen. In this case you pulled the RF board so I would take a hard look at Molex Connectror RF-3 and Pins 9 and 10 as this is path of cutoff and operating bias voltage from the bias voltage adjust pot. Also look at RF-2 connector. Common to have bad molex connector or bad crimp on lead wire or broken spring temper wedge on crimp. Suggest you keep the heaters turned OFF while you measure and monitor the bias voltage while you plug and unplug RF-3 and RF-2 to reseat them and then gently tug on the noted pins lead wires at

these connectors in the bias voltage path. You can see the path if you study the schematic. Do not put heaters back on until you are certain that you have stable bias at Pin 5 of tube socket lugs on the Final board. Lastly, it is possible that the Finals are damaged. You may want to remove PA cage cover and watch them when you are ready to commence loading. BE CAREFUL 900vdc Present. See any hint of color must quickly shut down. They will continue to glow orange even after down power as the cathode has been heated by the filament and after filament voltage is removed cathode emission doesnt stop instantly. This is the best I can do for you. Terry K9TW

55391. VFO Shaft/Knob Wobble - TS-530s

Hi,

Is there a fix for loose wobbly TS-530/830 VFO shaft. On mine both knob and 0-500 scale move up and down a good bit. I've pulled the VFO out and can see that there is play in the hole of the plate in front of the gear system. Doesn't effect the tuning, but if there's a fix - why not fix it?

The VFO-230 is an accessory and really not required unless you plan on working split or desire to have several memory channels. The TS-830S, as a stand-alone transceiver, wins hands-down receiver wise, overall other Kenwood hybrids. The VFO-230 requires AC power at all times, even when the TS-830S is shut down, in order to retain the memory channels and to keep the VFO display from displaying random numbers when you turn the TS-830S back on. I have a master AC switch that turns off all AC power when I'm not at the station operating position. So, each time I want to use the TS-830S with the VFO-230, I have to completely reset the VFO-230 to track properly and if I want my memory channels back, I have to add them all in again. Of course, when I kill all the AC power for the night, the next day I have to repeat the process; and the next day,, etc. The VFO-230 was not a great design for easy use and convenience. They're in demand now with high pricing probably because it was pricey back when it was offered, and they probably didn't sell a ton of them as they did with the matching speaker and antenna tuner so there are much less available on the open market.

Fix discussions in the past include prick punching the circumference of the hole in the metal plate that holds the shaft bushing to restore the fit and/or installing a thin belleville washer behind the c-clip retainer.

Probably can do keyword searches on archived messages and find these two "fixes".

A good machinist could probably come up with better fix. Axial play usually is slight, but with age radial play becomes excessive.

Charlie,

I think you may be confusing the TS-530/TS-830 solder mounted relays with the socket mounted relays in the TS-520's?

Brian,

The TS-520's have 2 relays that are mounted in sockets. Both relays can be removed and cleaned.

See the TS-520 Service Manual, page 38, to locate and remove the 2 relays.

Both relays are closed frame relays (the contacts are enclosed in a plastic cover). To clean the relays simply use the following procedure. When removing, handling, and installing the relays, use care to ensure you do not damage the relays. I've used the following procedures and have excellent result cleaning the 520 and 820 relays as well as relays in other make and model of ham transmitters/transceivers.

The relay's plastic cover can be removed by gently prying the sides so the cover can be removed. Once the cover has been removed use care when handling the relay so as to prevent bending of the terminals.

Slide a piece of bond paper wet with contact cleaner between the relay contacts. Use a new piece of paper wet with cleaner each time until the paper no longer turns dark/black. Placing the paper between the contacts will require you to "carefully" move the relay armature manually with your fingers.

Once the relay terminal cleaning process is completed use generous amounts of canned air (available at Walmart) or compressed air to remove any remaining cleaner. The canned or compressed air should remove any/all cleaner residue from the relay contacts and relay contact metal strips so there is no cleaner remaining. Visually inspect the relay contact strips and relay coil to ensure all cleaner residue is removed then replace the plastic cover over the relay.

To clean the relay pins, use an old tooth brush wet with cleaner to gently clean the relay pins on the bottom of the relay. Use generous amounts of canned or compressed air to remove residual cleaner left on the bottom of the relay. Install the relays back into their sockets and replace the Marker and Vox Unit boards.

Ensure to follow all warnings labels on the contact cleaner can!!! Wait the designated time period, as stated on the cleaner's label, before applying power.

Topic: 55396 Message: 55402

That's understandable Charlie, no problem.

This does happen now and then where the TS-520/TS-820 relays are assumed to be the same as the TS-530/TS-830 relays. While the 530/830 relays are 4PDT (4 Pole Double Throw) relays and operate off of 12VDC, the design and method of mounting of the relays are entirely difference.

You are correct when referring to the TS-530 and TS-830 relays. When they fail, cleaning them is not an option. I've tried cleaning the relays in the 530/830 which, as you said, resulted in limited short term success. Replacing the relays in the TS-530 and TS-830 is the only fix. Ken, K4EAA, has a replacement relay to replace the relays in the TS-530/TS-830. The replacement relay consist of 2 Axicom D2n relays on a small PC board that mounts in the same place as the original Aromat NF4EB-12V used in the 530/830.

For those looking for replacement relays for their TS-530/TS-830, there is an eBay seller who is selling the Aromat NF4EB-12V 4PDT relay that is used in the 530/830 and other KW TS-120/130 transceivers. The eBay ad is #322214293181 with a price tag of $19.95 plus $2.45 shipping for one relay.The same seller is selling packs of "2 relays" under eBay ad # 322214293198 $29.95 plus $2.45 shipping. The price for each relay in the 2 pack would be $14.98 verses $19.95 for a single relay. Both eBay ads, the seller says he has "More than 10 Available". The relays in the above eBay ads appear to be "new" relays, not relays "pulled" from PC boards.

The following website sells replacement 520/820 relays

http://www.hybridrestore.com/parts/

or you can drop Walter Dilley an email walterdilley@..., to see if he has spare 520/820 relays. Walter has numerous KW hybrid spare parts.

55403. TV-506 Transverter

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-08-22 20:55:20 UTC
From: Ken Bain
Topic: 55403 Message: 55403

A little background before I ask my question...

I currently have two Kenwoods in my shack; TS-520S and TS-830S. Since I got the 830S, my 520S has been collecting dust with the occasional power up to play with it. I've had that rig since high school and just can't bring myself to part with it. So, I'm considering breathing new life into it by getting a TV-506 transverter and using it for 6 meters. However, I haven't heard much about the 506 and wanted to get some feedback from the group on the 506's performance with the 520S. Thanks in advance!

Ken AA5CF

Ken,
Both the TV-506 & the TV-502 put out the same power...about 16 watts and use the same cable. If you do not already have the TV-506, I would look for the matching VFO-520 to compliment your 520S, more versatile. Both transverters are hard to find especially if they have an interconnect cable! The interconnect cable ends...are pretty much "unobtanium." You could connect with individual pins at the end of each wire. Just my dollars worth(adjusted for inflation)

Ken, I had a TV506 to go with my TS520, it had a rather deaf receiver converter and it was within specs. rather than installing a FET amp inside it I left it unmodified and sold it. I had much better reception with my old Teacraft nuvistor converter into a Hallicrafters SX101 reciever on the "converter" band (I believe it was 30.5-34.5 MHz on the Hallicrafters). I could hear signals on the older gear that the TV506 could not even detect at all when using the same antenna. . My radio is Ham Radio...CW is Real Radio 73, John...K8JD

Ken: I concur with Joe and John. You might look for a Parks 6M converter (mfg in Portland. OR area) or a Drake SC-6 6M above S/N 300 or so. The Parks is a Nuvister unit (w/ its own PS) and the Drake is SS. Both are very nice performers.

Good luck - Joe k7mks

Hi Ken,

While the deafness of the TV-506 is well known I suppose it depends on what you want to do. Is it the case of wanting to get a matched Kenwood system on the air? If so you might be better off putting a preamp in the transverter. If you want to be serious on 6m you might consider a better performing transverter as has been advised by others. If you want to play 6m occasionally then waiting for sporadic E openings could give you all the fun on 6m you need. Signals are ridiculously strong during these openings and contacts can be made on the proverbial wet string. Your TV-506 might not be a handicap in this case. A serious entry into 6m requires a whole other discussion which I'm sure has no place on this forum.

Thanks Lou (and others). This is exactly what I was hoping to gain by starting this conversation. I've never really contemplated getting a transverter before and since I have a shack full of Kenwood gear, the 506 seemed like an obvious choice. I was unaware of the sensitivity issue before this thread. I'm much more concerned about performance over cosmetics, so I'll look into better performing transverters than the 506.

Thanks y'all!

To continue the thread and inform those who may be following it, I have sorted the actual original failure that was reported by the owner of the second rig (TS-530S) I have been working on.

To give a round-up of the tasks completed.

All the visually and measured suspect/ failed items were replaced, but when it came to C9 the snubber
used in the 3.5 MHz section, the cap here was replaced with a Class II 6kV 100pF device. This proved to be inadequate for the purpose, pointed out by Terry K9TW as probably needing to tolerate 500V or more of RF in the circuit and coping with more than 2 Amps circulating in these components.

The originally described fault noticed by the owner, was concerning tuning up on 3.5 MHz and not being able to achieve power out and finding the power dropping away. C9 was definitely severely toasted and measured 135pF out of circuit. When the replacement 100pF device was put to the test, it exhibited similar symptoms as the failed original. On removal it measured 117pF, so was unable to cope with the RF stress, as was the aged and damaged original. The Class II device buckled at knees and would have been unlikely to survive.

I went back to work on deciphering the part numbers of Murata caps I could obtain from my supplier and
identified Class I, 3kV 100pF and tonight, one was fitted in place and voila, the sweet vision of a solid,steady 100 + watts on 3.5 and 1.8 MHz was obtained.

Thanks for the supportive comments from David and Terry, another TS-530S goes on the air again for a few more years.

Best Regards
Al

55414. TS-830S Birdies

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-08-23 17:11:38 UTC
From: rrmvargo@...
Topic: 55414 Message: 55414

Hi-
I've a TS-830S that has low level birdies on every band. 2.000MHz, 4.000MHz, 3.5/3.6/3.75MHz, 7.343MHz, 14MHz, 18.476MHz ..... to mention a few. The tones are affected by the carrier offset for the mode chosen.

These birdies do not register on the S meter & some are low enough that air noise will cover them up. Others shine thru the air noise.

I checked D1 on the RF board & on the diode checker it measures 0.6VDC fwd & Infinity reversed. When I power the rig, I measure 8.8VDC Cal OFF & 1.8VDC Cal On. So D1 seems to be working OK.

Any other thoughts?

Thanx - Bob W8RMV

Thanks for the closure. Especially useful to those who follow the thread and/or are contemplating similar repair.

Substituting a high voltage Class 2 will work sometimes from perspective it wont go off like a fire cracker, but many times especially in padder service the change in capacitance that occurs with dielectric heating results in de-tuning the involved parallel resonant circuit.

Hi Terry,
The birdies are there either way, connector 4 on or off the RF board. It was the first place I looked.

The birdies are very close to being aligned with the Cal frequency in some cases, but not quite.

Searching past posts, I have not seen too many "birdie" investigations on 830's.

Thank you very much Gary!
It is all set up in the shack and will remain in use for years to come, a beautifully cared for excellent rig in great condition. For my operating style I prefer the simpler 520 and love operating it, and was very grateful to receive this to replace one that was in much worse condition and that I had burned out the transmit section out on and had not been able to get working again.
This came with an added bonus of possibly getting my 15 yr old son in the hobby too since I have now boxed up my IC-7100 for him when he gets his ticket. He took a tech class a couple years go but never tested, I am hopeing this will be the motivation he needs to get going again, he says it is anyway.

OK the unplugged mini-coax near TP-1 on RF board is acting like antenna. If you plug it back in and unplug Conn 4 on PLL board the birdies should go away.

The few times I have encountered this I was able to fix it by replacing D1 block diode with a 1n914 or 1n4148 (ultra fast switching diode).

It is also possible that the bias divider resistors R1/R2 have changed values although I have never personally seen it. There is usually enough of R2 lead exposed that you can get on the center of the divider with DMM. Should see something around 4.8vdc.

You may be able to unplug Conn 4 at RF board and jumper in another fast switcher diode in series between unplugged molex connector and mating connector pin. Try inserting diode lead down inside the unplugged conn and then touch free end of diode to mating connector pin.

Not an easy space to work in.

Hi Terry,
Pulling the 2 pin marker connector on the PLL board did not remove the birdies. There is a birdie at 7462.3 in Tune mode, that is my test freq. And I measure 4.8VDC at the R1/2 divider.

I'll try clipping the old D1 and I can cobble in a new 1N4148. I've a 100 of those, so I can waste one..... unless you have other ideas before doing so.

Thanx Bob W8RMV

Bob:

I asked you previously to unplug Conn 4 on RF board and see if the birdies on all the bands went away and you said you did that and the birdes are still there. I then said the unplugged Conn 4 laying in close vicinity to TP-1 is likely coupling the rf output from the unplugged mini coax acting as an antenna. If that is the case then unplug the other end of the mini coax at the PLL board and should be no RF radiating and coupling in to the RF board via the unplugged coax which when you unplug it may be laying close to TP-1. Was trying to explain why you still had the birdies on each band with Conn 4 on RF board unplugged and no marker signal directly connected to Pin 2.

I wouldnt trouble shoot this by just monitoring 40 meters. It is normal to have a weak birdie around 7.338 to 7.342 with normal strong 25 khz markers at 7.325 and 7.350 with the marker on. Should only hear a weak birdie around 7.342 (lsb) with Marker turned off.

OK you have the correct foward bias on D1 so the divider resistors R1/R2 are OK.

I know you tested D1 and said it is good and not shorted and not leaky. Try one more thing. Pull Conn 4 again and with the rig downpowered measure resistance from Cathode of D1 to chassis ground. Should read approx 260k to 285k ohms and with DMM leads reversed should read infinite.

Bob:

Did you measure from the actual cathode lead of D1 and not just Pin 2 molex pin? Could be a high resistance molex pin solder connection?

My notes show 260k to 300k ohm from the cathode lead (top lead of vertically mounted diode). I do have couple of 830s here and would have to remove covers to make the measurement. Can do that if we need to.

Do you have a 1N914 or 1N4148 that you could measure?

Terry,
I measured at both locations, same result.

When I measured a few new Philips 1N4148's I have, they measure 1.5-1.6M. So the one in the 830 does measure a bit higher at 1.9M. I measured them with my Fluke 189 which has ~0.5VDC at the leads.

No need for you to pull the covers on your 830's. Thanx for the offer.

Topic: 55414 Message: 55427

I assume 1.6 meg is forward biased? If so, what does it read with Fluke leads reversed? (OL?)

With Marker off should read approx 4.0 vdc across D1 and with Marker on should read very close to 0.6 vdc across it.

Do you have O-scope? If so connect probe to anode of D1 with Conn 4 landed and the Marker switch off. Should see approx 2mv P-P @25khz (no greater).

I have seen this problem probably only 3 or 4 times and each time D1 was the culprit. D1 is called out wrong on the 830 schematic and is correct on the RF Board PC view in the Service Manual. It is a 1S1587. Has approx 2ns reverse recovery and 2pf junction capacitance which is about half that of a 1N4148. I dont know of a source for 1S1587.

Part of problem is that there is 100khz sync reference applied to multivibrator at all times as well as 9vdc collector and bias voltage. MS line is switched to ground to ground the transistor emitters and turn on the marker signal and forward bias D1 through resistor R159 1K on the PLL board. A leaky or shorted diode couples these odd ball markers thru C5 on the RF board even when the Marker switch is off and there should be no dc ground path to the emitters. There is an RF ground thru C183. I suspect these odd ball harmonics are there all the time and just not heard with a good D1 turned off hard.

I am not telling you to pull RF board and replace D1 just what my experience has been.

Hopefully you can find and fix and report back so we can catalog if some failure other than D1.

Topic: 55428 Message: 55428

Hello to the group, and thanks to the moderators for allowing me to join. For background, I am a tech for a surplus electronics store that deals primarily in military and commercial equipment. We occasionally take in amateur radio equipment, primarily from hams and estates in the local area, which, in my spare time, I clean up, check out, and repair when possible. I have been doing this for three years, and have repaired several Kenwood rigs, including hybrids.

I have a very good looking TS-820 on the bench which had the usual problems for a rig that has not been used in some time, corroded contacts, misalignment, weak driver, improper neutralization, etc., all thing I've corrected before. It has one problem which has baffled me, however - I cannot get the rig to properly load on transmit on either 160 or 80 meters. 40 meters loads but with the plate control well into the "3.5" region, while 20 and up load normally. I am loading into a Heathkit Cantenna, and monitoring the ouput signal with an external wattmeter and a 100 Mhz oscilliscope attached to the ouput monitor connector. I see about 40-50 watts output on both 160 and 80 on the wattmeter, but very little output actually visible on the 'scope. Plate current does not null properly on either band.The coil pack unit has been tuned up per the service manual, and receive on all bands is excellent. Drive control tunes normally, and there is plenty of ALC current.

If this was happening on a higher frequency I would have said that the final section is going into parasitic oscillations due to either improper neutralization or some fault in the drive circuitry, but the fact that the upper bands are transmitting cleanly and with proper ouput lead me to suspect another culprit. I tore apart the final compartment and checked all the components associated with 160 or 80, finding one discrepancy. C7, the 1000 pf disc ceramic cap attached to wafer section S4-4 read low capacitance, around 850 pf, and I cried "Eureka!" .... too soon, as it turned out. After replacing it and reassembling the compartment, I discovered the situation was virtually unchanged.

So here I am, hat in hand, asking if anyone has ever experienced this particular problem, and if so what was your solution. Thanks in advance for any clues you can provide.

Just the basics Paul ,
Got HV ? If the upper HV filter cap has given up voltage will read 666
rather than closer to to 1000.
Check the 6.8uh choke at the bottom of the plate choke .
Speaking of plate choke ....?
Of course the screen and cathode resistors
After one last look at the base of the plate choke and associated caps for
obvious damage and possible shotgun replacement (as in screw it just do it
) I'd be in the same shape as you .

Paul:

Good write up. Couple of things.

1. Are you looking at the output from the RF detector circuit on the Cantenna with your O-scope (RCA jack output)? If so, it is DC and not RF and has no correlation to RF output power. It is just Relative RF output power and could be used to load the radio in lieu of using the internal RF relative power meter position and/or an external wattmeter. This circuit is very frequency sensitive and the DC voltage that is available at the jack on 80 meters will be much less than what is there on 10 meters. There are some mods out there to add some frequency compensation capacitors to make the dc output voltage more linear across the operating bands but not really needed today.

2. Make sure Plate voltage meter indicates approx 900vdc. If it indicates approx 450 vdc you have lost one of the two HV filter caps, but that should affect higher bands as well.

3. If the unit has a white nylon bandswitch coupler make sure it is not cracked and the two bandswitch shafts have not slipped out of sync and the S4 switch isnt selecting the wrong tank coil taps.

4. What you describe sounds like bad fixed padder caps or bad bandswitch contacts not switching the padders in. If you have a digital LCR bridge you can measure the total capacitance on each band. Have to lift L4 safety choke and R8 RF detector voltage divider resistor. You can see approx correct total capacitance for each band on Jim Showkers Hybrid Restore website.

5. Lastly make sure that the Plate Tank and Plate Load cap couplers are not loose and shafts have slipped.

In the early 70s I spent many wonderful trips to Fair Radio Sales!

Terry,
Yes I checked both forward (190M) & reverse bias (infinite) on the 1N4148. At 100kHz test freq I measured 6pF.

So I just clipped the original D1 and installed the 1N4148 to no avail. It still has the birdies. I did notice a few things:
The birdie is on the low side of 3.6MHZ where the Cal signal is on the high side. ie- to zero beat 3.6MHz with the Cal you start high & move down to 3.6MHz. Where with the birdie, you start below 3.6MHz.

Another observation is the shaft on the mode switch stand proud from the face of the rig as if it is almost not engaging all of the mode switch, yet it seems to work fine.

Lastly I notice 2 blue filters on the IF board near the front of the radio towards the VFO CF1 A & B (?). My other 830 has only one that bridges across where the 2 filters are on this older (earlier SN) unit. Maybe that was a later design change.

I appreciate the help, and we will let this one go for the time being and return the frequency back to normal amateur use.

Topic: 55428 Message: 55434

1. Yes, Terry, I am, and I'm aware of the problem. I expected a loss of sensitivity, however the 'scope shows such a low signal on 80 and 160 that I think I could've just linked the driver circuit directly to the Cantenna and gotten more response.

2. Plate voltage runs approx. 950 no load, sags to approx. 900 on xmit, according to the 820's meter. Not having any issues with the meter otherwise, so I would tend to accept that, but I'll dig out the HV probe and check.

3. First thing I thought of, we happen to have a military radio that has brass couplers in it that fit nicely and I've changed them in a couple of Kenwoods before. This one is the older phenolic coupler, and is holding firm.

4. The cap I mentioned is one of the padders. All the rest measure good on our Digibridge, I might go ahead and shotgun the rest, as the Digibridge doesn't measure at high voltage. Engaged contacts measure near zero resistance with a DMM.

5. All tight and no play.

Thanks for the runthrough, always good to make sure all the I's are dotted and the T's crossed. By the way we've missed you, come back soon!

Thanks, Dennis, for the tip, I didn't think to check the 6.8 uh choke's value, just its continuity, will have to put it on the Digibridge and see. Plate choke base is nicely white, coils are still coppery not burnt, and show continuity. Screen and cathode resistors were the second thing checked, after the bandswitch coupler. Thanks for your prompt reply.

Topic: 55428 Message: 55436

The TS820S VHF choke is 3.1uhy. The TS530/830 is 6.8uhy.

Best way to check the RF plate choke is to use GDO or Sweep with Impedance bridge or Spectrum Analyzer or VNA and check the Parallel resonance frequency and the Series Resonant holes to make sure they havent shifted.

Have to unplug the parasitic suppressors from the Final tubes and lift the Plate block cap off. Loosely couple the GDO to base of choke with a short applied across the windings. The dips you see are the series resonant holes.With short removed will see the parallel resonance frequency where choke works best (high impedance).

Choke on the bench looks like this:
1. 235 to 240uhy
2. Parallel resonance approx 11.5mhz
3. Series resonance 18mhz and 45mhz

Very rare for L1 to fail but possible.

The purpose of these small VHF chokes in series with the main RF Plate choke is to "wide band" the choke so that it has sufficient high impedance from 1.9 to 30 mhz with no series resonant holes parked on the operating bands. A tall order. The low height of the PA cage prevents installing a tall space wound solenoid style RF plate choke so KW added the small VHF choke at the base and oriented at a right angle to reduce mutual inductance coupling effect. It is there primarily to ensure that there is sufficient high impedance to allow 160 meters operation.

From: wagstw46@...
Topic: 55428 Message: 55437

1. At full load should see something on order of 825vdc at top of the RF plate choke.

2. Red/Brown fibre couple is in the early production runs and it doesnt crack or break, but over zealous tightening of the lock screws can strip them out.

3. There are fixed padders switched in shunt with the Tank Cap and the Plate load cap. Tank cap padders not too hard to access. Not easy to access and/or change individual ones on the Plate load cap as they are stacked like coins close together at base of Tank Coil and sometimes installed under the Tank coil. Better to shoot the combo than try to shot gun them individually. Easy to lift one end of couple of components and fully mesh Tank and Load cap plates and shoot all. On 160 should see approx 5100pf and on 80 should see approx 2900pf. Can also place Coax tee on SO-239 and solder trial padders across a PL-259 and screw on open Tee and see the effect.

4. Lastly, measure the Screen Grid voltage at the Final tube socket on 160 and 80 to ensure full voltage key down. There is an interlock installed on some of the TS820 production runs that supplies SG voltage thru S4-5 which is on the bottom of the S4 switch and hard to access for cleaning. High resistance on this contact can reduce screen grid voltage which has significant effect on RF output. Pretty easy to bypass this interlock and just land 210 (wht/brwn) lead wire on PD2. The idea was to make sure Finals were off for JJY/WWV band switch position. I doubt you will be trying to load with BS in that position. I dont normally recommend mods or defeating interlocks but make an exception in this case.

I was questioned off the forum about measuring DC plate voltage at top of the RF Plate choke in TX mode keydown full load. This is a good question as your DMM may not like the presence of high RF voltage.

The point I was trying to make is that just because your panel meter displays HV it doenst mean there is HV at the anode caps of both Final tubes. Can have open VHF choke, open RF plate choke winding, bad solder connections or broken wire at either end of RF plate choke winding, bad solder connections at the parasitic suppressor solder lugs.

Best to confirm there is voltage at the base of the RF plate choke and at the plate caps of both tubes. Can measure loaded B+ supply at base of the choke in TX mode and can measure at top of Plate choke in Rx mode. Best to measure at downstream end of both of the parasitic suppressors as common to have badly sublimated solder connections at the solder lugs. Not uncommon to lift a plate cap off and find yourself holding a free parasitic suppressor in your hand and see a perfectly fitted hole in the sublimated solder where you just pulled the suppressor lead out. If that happens remove as much of the old solder as you can, re-land the suppressor on the tubes plate cap and then re-solder.

Yes you could measure top of RF plate choke in TX mode using an auxiliary RF choke in series with your red DMM lead, but I dont recommend this especially if you are going to use clip leads and have them along with the choke laying on the bench where accidental contact could occur. Just measure at base of RF plate choke in TX mode and at parasitic suppressor leads at the tube plate caps in RX mode.

I appreciate a question like this.

55439. TS-820 transmit audio problem

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-08-31 15:03:47 UTC
From: zehrhj@...
Topic: 55439 Message: 55439

My TS-820 is working fine on cw - 100 W out. On SSB, however, the transmitted audio is good when the ALC is turned down to maybe 5-10 W output (processor off). When the gain is turned up so that the ALC is in the normal range and output is increased, however, the audio becomes distorted. I have tried several mics, including my MC-50 (which works fine on my TS-830s).

Any suggestions about what might be going on?

Thanks and 73

Howard,
I suspect that you are over driving(over modulating) your signal. Power output on CW as you state is 100 watts...quite normal...since CW is a constant signal input. Your SSB output appears normal also, since you do not state if you are using a "peak" or "averaging" meter. The proper way to set your "ALC meter reading" has been the subject of many conversations in the group. The directions in the manual are a bit confusing. The consensus is that you should advance the "MIC" control just so the meter needle just barely comes up on voice peaks when speaking into the mic in a normal voice level. Over modulating leads to "splatter" and is not good amateur practice.

Topic: 55439 Message: 55442

Howard,
When speaking into the mic at normal audio level, you want to see about 1/4 to 1/3rd of your peak plate current reading. So if in CW at 100w output you see say 230ma, then speaking at normal level into the mic you would see maybe 80-90ma on peaks. If you had a peak reading watt meter, you would be seeing 100W output on voice peaks.

As long as you can get that, with good audio reports, then you don't have to look at the ALC meter. Just get into the habit of monitoring the IP reading.

Hope this helps.
Mark, WB0IQK

Topic: 55439 Message: 55444

I have it on the bench now. Bias is 60ma. On cw, plate current is 230.

In LSB (80M or 40M), into a dummy load, with the mic at 1/2 (higher than I think it should be) there is maybe 10W output on peak, and the current barely moves. Monitoring with headphones, the audio sounds fine but if I turn the mic gain up further, it distorts.

I've mostly used this on cw but I have used it on 40M SSB and don't remember this problem. However, it has been a few months since I used it. I wonder if I should try cleaning some contacts and ground connections

Thanks
Howard K4LXY

Sounds like you have a failed componant in the Tx audio chain, you may want to trace it out with an O-scope and audio generator hooked to the mic input. My radio is Ham Radio...CW is Real Radio 73, John...K8JD

Further testing: Again, on cw RF output is normal; current about 230ma.

On SSB, current peaking about 100ma or so. However, rf output is low (I compared with my TS-830s to double-check). If I turn the mic gain up past 1/2, I can get somewhat more RF but the audio gets garbled. Any suggestions where I should start checking?

(Using an MC-50 mic in high impedance position.)

Thanks

It does sound like something in the TX audio chain. The troubleshooting chart mentions a microphone amplifier generator board, which I have yet to locate. But I'm just starting.

Topic: 54481 Message: 55448

Welcome to the Yahoo Kenwood TS-520_820_530_830 Amateur Radio Group. This group is comprised of members who's interest is in maintaining and operating the Kenwood TS-520, TS-820, TS-530, TS-830, TS-510, TS-511, T-599/R599 and R820 Hybrid transceivers, transmitter and receivers. In addition, the group supports discussions covering the associated Kenwood accessories such as the VFO-520, VFO-820, VFO-230, and VFO-240 remote VFOs, the Kenwood antenna tuners, and the various Kenwood desk and hand microphones.

This is a restricted group requiring membership approval prior to receiving and posting messages to the group. To join the group simply complete the Yahoo Kenwood TS-520_820_530_830 Group's application process by clicking on the “+ Join Group” icon on the group's homepage. Select the desired method of receiving messages by clicking the appropriate radio button, then provide a brief description about yourself to include: your first name, your Amateur Radio call sign, your interest in the Kenwood hybrid radio, and the model of Kenwood hybrid you own, operate, or in the process of purchasing in the text box provided. If you are not a licensed Amateur Radio operator, no problem, simply complete the application process and provide the same information less the Amateur Radio call sign. Once you have completed the text, click the Join Group icon. Your application will be reviewed and approved by a group co-owner or Moderator. If you leave the application text box blank, your application for membership will be rejected. Simply reapply and provide the information requested and resubmit your application for membership.

New members are placed on a "Moderate" status. This means that any message a new member posts to the group must be approved by a group co-owner or Moderator before it appears on the group server for all members to see. The length of time a new member remains in a "Moderate message status" is determined by the members ability to adhere to, and follow the group's policies. The faster the new member(s) can prove they are adhering to, and following the group's policies, the quicker the new member's status will be changed to “Allowed”.

The “Allowed” status means the member can submit/post their messages without group co-owner or Moderator's approval. A member who's message status is set to “Allowed” may have their message status changed to "Moderate" if it is deemed necessary by a group co-owner or Moderator for one of the following reasons:

1. Failure to follow the group's policies after being informed by a group co-owner or Moderator
2. Knowingly violate any of the group's policies
3. Any improper behavior by the member that is deemed inappropriate by a group co-owner or Moderator

The group is moderated by both group co-owners and group Moderators. While we would like to have a group co-owner and/or Moderator present 24/7, that is not possible, as group co-owners and Moderators have a life too. Therefore, there will be times when a group co-owner and/or a moderator will not be present. This will affect the time a moderated member's messages may take to get approved/rejected. This occurs most often during major holidays Also, the group's server is not maintained by the group co-owner(s) or Moderators.

Therefore, when Yahoo has problems affecting Yahoo Groups, ALL members will simply have to wait for Yahoo to fix the problem. Group co-owners and Moderators also do not have any control over how the group's server handles attachments to messages or how message search results are provided.

Page 1

As stated above, this group has a set of policies that all members must agree to and abide by. If any member, new or old, that feels they cannot accept the group's policies, that member is free to terminate their membership at any time without notifying the group co-owners and/or Moderators.

Group's Policies:

1. Profanity of any type, regardless of the word and/or phrase(s) used in a message, is not allowed. This includes the use of abbreviation to improper words, use of symbols to substitute for letters, etc. In short, the use of profanity is NOT ALLOWED, PERIOD!!! The quickest way to get banned from this group is to use profanity!!!

2. Disrespect/Flaming any member regardless of the reason, is not allowed.

3. Taking over a thread by a member that changes the threads original subject and content, is not allowed.

4. Messages that contain as part of the message text, discussions of a member's private life are not allowed. Responses to messages are to pertain to the original message subject.

5. Long discussions that are products of an original messages are not allowed. If there are 2 or 3 members who wish to discuss a subject in more detail and at great lengths should take their discussions off the group and continue their discussions using private email addresses.

6. MESSAGES THAT DO NOT CONTAIN ACCEPTABLE MESSAGE SIGNATURES, WILL BE SUMMARILY REJECTED! It takes less than 5 seconds to ensure your message contains an acceptable message signature. There is no excuse for not adding a message signature to your messages. Political or religious signatures/statements are not permitted.

The following are examples of the ONLY acceptable message signatures:

Licensed Amateur Radio members:

Example:
“73s
John WA1ABC”

Non-licensed members

Example:

73s
Mary

If a member does not wish to include their Amateur Radio call sign in their signature, then simply use their first/given/Christian name ONLY, same as non-licensed members.

Each message signature must be positioned at the bottom of the message text and separated by at least one line.

For example:

Hi John,

Yes capacitor C25 is the right cap you should be checking. For details, review the schematic.

73s
Bill

Screen names such as JLH524 or MWPO125 are not acceptable message signatures. Screen names are acceptable ONLY when used as part of the member's email address.

The member's email address is not an acceptable message signature, regardless whether the member's name appears in the email address or not.

A member's “initials” are not acceptable as a messages signature.

A member may add up to 2 additional lines to their message signature. The additional 2 lines may contain a link to the member's website and a link to the member's Amateur Radio club etc. The addition of 3 or more lines to the message signature, listing the many different clubs the member belongs to, the positions they hold within the respective club(s), their professional position within the company the member works for, and other information is considered excessive and not allowed. The following is an example of an acceptable message signature containing two additional line:

73
Mike-w5rkl
www.w5rkl.com
Yahoo Kenwood TS-520_820_530_830 Moderator (Mike-w5rkl is no longer a Moderator, but used as an example--tnx)

In the past there have been members who state our group policies are too strict. We maintain strict group policies for 2 simple reasons:

1. To maintain good order and discipline in the group.
2. Provide a friendly group where all members are treated equally and an environment free of improper behavior

73
Yahoo Kenwood TS-520_820_530_830 Hybrid Group Co-owners and Moderators.

55449. File - Rules, For Sale or Want to buy Posts

Yahoo group: TS-520_820_530_830 (2015 — 2016)

Topic: 54620 Message: 55449

Rules pertaining to Occasional For Sale and Want to Buy Posts.

Members of the TS-520_820_530_830 Yahoo Group who have been members for at least 30 days may place " for sale" posts no more frequently than two in any 30 day period." Want to buy" posts are permitted immediately upon membership and are limited to 2 in any 30 day period.

For sale posts are limited to the sale of TS-510, 515, 520, 820, 530, 830, and the 599 series twins, as well as Kenwood accessories intended for use with these radios.
Also, group members may post "service equipment" for sale. This may include, but are not limited to: vtvms, various signal generators, and other testing/service equipment. Posts must include: the make and model of the item for sale, as well as an accurate description of its condition, and the asking price.

When the item is sold, please make a short post to that effect.

Replies and discussions regarding these posts must be taken off of this group either by direct e-mail to the seller or as directed by the seller.

Buyers and sellers are on their own. The TS-520_820_530_830 Yahoo Group, its owners, co-owners, moderators, or members other than the seller, hold no responsibility for the accuracy of the posts or the credibility of the seller or buyer.

We do not expect that members of this group will misrepresent, or in any way cheat other members. At the co-owners(s)/moderators discretion, we may choose to ban any member from making further for sale posts, or ban the member from this group entirely if we believe their posts or transactions are not of the utmost integrity.

We ask that those who buy and sell equipment as a main business not post here. We will allow posts from members who occasionally restore and sell equipment/accessories as stated above.

We expect our members to use discretion. If excessive traffic develops as a direct result of these postings, they may have to be discontinued.

Walter Breining, N9WB
Joseph T Stiles, WB7UQU

Howard:

The Troubleshooting charts are sadly pretty useless. I would caution about using them as if followed literally you will be replacing a lot of good active devices. The mic amps are on the IF board . See Q19,Q20,Q21.

Couple of things:

1. Setting the Mic gain pot to #5 or 12 Oclock position is not unusual when using a MC-50 or MC-60 mic.

2. Never act solely on the basis of a single off air report of bad audio or adjacent frequency splatter. There are plenty of folks who could not accurately tell you if you had RF on your audio. I would go to a net and get multiple reports before I took any action. Here in midwest can check into Midcars at 7.258 or 7.255 and ask for an audio check and find more than one person will typically respond including a few who can tune across you signal and give you a meaningful report.

3. With the Moni on and listening with headphones (turn off SG switch as you dont need the Finals) do you hear the same audio distortion in LSB and USB when you advance the Mic gain pot? Also, does your voice have the same frequency response or is one bass and the other treble? It would be normal to hear some distortion using the Moni on both LSB and USB as you advance the mic gain pot from 1200 position to say around #8 or 3 Oclock. I know of no microphone with "normal speaking voice and distance to the mic) that would ever require advancing the mic gain pot very much past #5 or 1200 position. In fact a hotter mic like a Shure 444D would see probably no more than the #3 position. This of course assumes radio has been aligned for accurate ALC indication.

4. It is possible that you may have an issue with IF Filter or Carrier Osc set point adjustment. When you flip back and forth from LSB to USB in RX mode does the back ground noise have same tone ie bass or treble sound? With carrier set point properly adjusted for 6dB roll off around 300 hz you should see no more than approx 25 watts maximum on voice peaks on an average reading wattmeter. 10watts to 15 watts would be typical level unless close talking and yelling in the mic.

4. Lastly, It is extremely difficult to over drive a TS820S or TS830S as both radios in addition to ALC employ RF Negative Feedback. It would be unusual but you can check the RF board and make sure that the NFB lead wire and the Driver tube neutralization lead wire RNC are tack soldered in place. It is possible if someone removed the RF board that they forgot to reland these two lead wires.

5. I of course cant hear this distortion, but I am wondering if the 10 watts you are seeing as you modulate isnt normal. Plenty of folks who load to 100 watts in CW mode and expect to see similar output power indicated on their wattmeter in LSB/USB. Only way for that to happen is a sustained whistle in the mic.

Terry K9TW

Greetings group,
  A short notice that due to the up coming Labor Day holiday weekend...also known to other parts of the world as a "bank holiday," for those members who are "moderated" or otherwise post a problem/question, you may see a significantly slow response.
Stay safe and have fun. I'll be operating /7 qrp from grid CN87jk as time/conditions permit on 20 meters(ssb) and 40 meters (cw)

Terry With the mic gain at 12:00, the monitored audio sounds pretty normal in USB, but I think there is some distortion in LSB Also, both received noise and my voice are somewhat more bass-y in USB; in LSB, the pitch is a bit higher. Does this suggest IF filter or carrier osc set point is off and if so, which should I work on first?

With the mic gain there and some ALC peaking, if I hold a hello I can peak about 40W.

Thanks
73 Howard

Topic: 55439 Message: 55456

The pitch as described isnt off enough to worry about it. Doesnt sound like a problem with where the carrier oscillator is being injected into the filter or a problem with the IF filter. You may need to inject audio into the mic line as suggested by another responder and look at it on O-scope. Not very common to have bad mic pre-amp/amp. I suppose you could change out the Balanced Modulator diodes. Some folks report improved performance with Schottky diodes like CDSH270 or 1N5711.

If you want to adjust the Carrier Oscillators the best way to set Carrier Point is the audio injection/wattmeter method. Need a good accurate and stable Audio or Function/Arbitrary Waveform generator to do this method. You load to 100 watts out into dummy load in CW mode. Then connect Audio gen to mic line and set for 1500 hz at 5mv and advance mic gain until you see 50 watts on wattmeter. The reason for this is it takes time to make the trimmer adjustments and no reason to have long keydown times on the Final and Driver tubes at 100 watts out. The procedure is described in Step 4-5 in the Service Manual. After setting the LSB/USB output power level equal to 50 watts at 250hz with VR-1 trimmer you go on to adjust the 6dB roll off at 300hz on LSB and USB. 6dB would be approx 12.5 watts.

Absent ability to inject low level audio into mic line you can use the Moni and adjust the Carrier Oscillator trimmers until your voice tone is the same on LSB and USB to your ear.

Another method is the Marker Zero Beat Method. Place AGC on Fast and adjust VFO for zero beat on LSB. Zero beat is a slow rythmic quiver of the S-meter needle. Adjust the LSB carrier oscillator trimmer cap for around S4 to S5 zero beat. Repeat for USB.

Some folks adjust the trimmers for same tone on just the receiver back ground noise and some do it monitoring a net that they are familiar with the net controllers voice.

Lastly, can be done with Audio Spectrum Analyzer software on Lap Top. Spectrogram works very well. You can see some traces on my website. Just need to make up a patch cord from headphone jack to mic line input on your PC. I have a log taper pot in my patch cord so I dont overdrive my sound card.

Adjustment of Carrier Oscillators has a bit of personal preference to it. Some prefer a more bass sound and others a more treble or communications presence (especially if running barefoot). Just remember how you set them in Rx mode is how you will sound in TX mode and vice versa.

What peak do you see on your wattmeter with the mic gain set to #4 position? Also, what external wattmeter are you using? 40 watts on an average reading wattmeter (like a Drake W4 or a Bird 43) is high in my experience. I would try using a Threeee-Threeee or a Fiveeeee-Fiveeeee as opposed to a Hello.

Terry K9TW

Hi all, I'm Sutton, AD0TY, and I've been working on my first tube rig. I acquired this rig for free from a local ham and decided to tinker and see if I could get it working. He had been using it as his main rig for years and when it failed seemed to be excited to have a good excuse to buy a new one. I started with no receive, no transmit, and no display. After reading a little I decided to remove the bandswitch and give it a make over. This evening I popped the rf board back in and got everything aligned. Yahoo! The rig locked and now I have a display! Unfortunately it still doesn't rx or tx. Doh! In receive the meter pegs no matter what it's set to and there is no receive audio, just a little crackle when the AF pot hits a dirty spot. If I try to tune up In Tune or CW mode, I get no ALC reading. In Tune I get no plate current on the meter (CW I get a play current of around 75mA that doesn't change). The meter reading for RF is zero. High voltage shows 900-950v. What would you all suspect? Where should I go from here?

Topic: 55457 Message: 55458

Regards pegged S meter: It is telling you that the AGC buss voltage is very low or missing.

1. Is RF gain pot full CW?
2. Measure RF-1 at Audio Board Molex Conn 11 Pin 5. Should be 3.2vdc
3. Measure RF-1 at IF board Molex Conn 12 Pin 4. Should be 3.2vdc
4. Need Hi Z meter to measure AGC buss at IF board. 10meg DMM will pull it down by at least a half a volt.
5. From time to time Q7 meter FET will short and pull AGC buss down.
6. Can temporarily power AGC buss with low Z power supply. Two 1.5 vdc D cell batteries in series. Negative to chassis ground and touch the positive to Molex Conn 12 Pin 2. If receiver comes alive you know that missing or very low AGC buss is the primary issue.
7. Aux relay on IF board (Flat Pack) is source of AGC/ALC problems. Can try tapping on the case. In any event recommend you replace it with K4EAA new relay board with plug in relays.

RF-1 is produced from regulated 9vdc on Audio Board. Confirm you have regulated 9vdc at Audio board TP-6.

RF-1 supplies both ALC and AGC busses so not able to peak Drive in Tune or CW mode may be due to no RF-1 at Audio Board. Suggest you focus on restoring the receiver first.

Sutton:

I forgot to mention you dont ever check or adjust zero signal/resting plate current in Tune or CW mode. Your Operating Manual on Pg 16 describes checking/setting it in SSB mode. I recommend turning the Mic gain pot full CCW. You dont want any output from the BM which would see TIF signal applied to TX Mixer and result in turning on Final tubes harder. If you were to use CW Mode to check it you would have to make sure that the CAR Level pot was full CCW. Just literally follow the instructions in the manual.

This is very helpful, Terry, and I've collected some of your earlier conversation on this topic as well.

For now I adjusted the LSB carrier oscillator by listening, and the transmit audio sounds much better - almost like the USB. And the received sound on USB and LSB is much more similar now.

With the mic set at 12:00 (using MC-50) and an MFJ power/swr meter on Peak, I get about 40-45W out on a sustained "hello," on both USB and LSB. Is this normal? It's just a bit lower than I get with the same meter and mic on my recently-aligned TS-830s. (My friend who wants to use this rig seems to think that is too low.)

You are a real asset to this group, Terry - thanks for taking the time.

Howard:

I know nothing about the accuracy or the meter ballistic characteristics of the MFJ wattmeter in Peak mode (I assume it has average and peak modes?). I would think that a sustained "HELLOOOOOOO" would result in 100 watts indication. If it has an average mode repeat your test and report back what wattage you see on voice peaks.

I think I previously told you that 25 watts would be about max on an average reading wattmeter and that 10 to 15 watts on a "hello-test- test-test" and not a long sustained "Hellooooooo" would be normal. The Peak reading wattmeters that I am familiar with will peak around 100 watts on SSB voice peaks especially with a sustained "HELLOOOO" or "TESSSSST". The indicating needle exhibits a charge and decay time constant similar to an RC circuit. I suspect this is what your friend is use to seeing? I have a new Bird 43P and frankly very seldom use the peak mode.

I am not sure of the point of whistling into the mic or using long sustained Hellooooooo in SSB mode as a standard operating practice? I suppose it gives some piece of mind? It is almost if you dont trust the ALC indication or plate meter swings? Time to worry is when you dont see normal ALC indications at your normal Mic gain setting with the mic you commonly use. Remember very few people had an external wattmeter when the TS820 hit the market. With its RF relative power meter position it was self sufficient rig and still is today. I like wattmeter loading of Class AB-1 linear amp and as a diagnostic aid when problems with coax jumpers and antennas, but wattmeter is not necessary to load the radio or to modulate it in SSB mode.

If you are getting approx 100 watts output at around 200ma Ip when you load in CW mode I suspect you are worrying about nothing. I believe Mark Gilger suggested or asked where Ip was averaging on voice peaks and if no more than 100ma then you are fine. A "hello test test test" would probably produce an average around 70ma to 75 ma. Looking at IP swings isnt what I would do. I would just modulate and keep the ALC peaks within the upper end of the black printed scale. As I previously stated it is pretty hard to overdrive a TS820S.

About time for the member owner operators of TS820S rigs who drive them daily to contribute their SSB operating practice and experience. Should be very interesting. I just work on them and have exhausted what I can contribute.

From: zehrhj@...
Topic: 55439 Message: 55464

Since the output is comparable to my TS-830s, which I know is working well, I'm convinced this one is about right. I did an on air test today and the audio sounds good now, too. I also pulled the vfo and cleaned contacts, so no more erratic readout (I had repaired the display earlier). I think I'm good to go. These hybrids sure sound a lot better than many modern rigs. Thanks for all your help!

55465. Hybrid Net Update (September 4, 2016)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-09-04 21:05:43 UTC
From: Mark Gilger
Topic: 55465 Message: 55465

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by me, WB0IQK. There
were 6 stations checking in under very poor band
conditions. The net was terminated early due to a thunderstorm in my area.

We had the following number of radios checking in.

1 running TS-520(x)
2 running TS-530(x)
0 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running TS-515
0 running 599 twins
0 running TS-900

I was running my TS-830s + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
11 stations checking in VERY, VERY POOR band conditions.

We had the following number of radios checking in.

2 running TS-520(x)
0 running TS-530(x)
0 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
1 running TS-900

I was running my TS-520s + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 ☐ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins

November 2015, Saturday net total = 66, Sunday total = 46
December 2015, Saturday net total = 55, Sunday total = 73
January 2016, Saturday net total = 129, Sunday total = 81
February 2016, Saturday net total = 98, Sunday total = 72
March 2016, Saturday net total = 74, Sunday total = 35
April 2016, Saturday net total = 101, Sunday total = 57
May 2016, Saturday net total = 51, Sunday total = 32
June 2016, Saturday net total = 39, Sunday total = 46
July 2016, Saturday net total = 52, Sunday total = 54
August 2016, Saturday net total = 28, Sunday total = 35
September 2016, Saturday net total = 5, Sunday total = 11 (Month to date)

55466. Cleaned the Relay

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-09-05 09:12:50 UTC
From: bsa0791@...
Topic: 55466 Message: 55466

I cleaned the relay on the underside at the rear of the TS 520. It still has the delay problem. For example, when I power the unit on, everything light up as normal as if it is on, silence from the speaker. After a few seconds, the RX will suddenly come in as normal. When it does it on CW, when I release the key, I will hear the relay disengage, and it takes varying time on each episode, and then the rx comes in as normal. Is there another relay I am missing? I installed an external vfo to check that circuitry and I have the same issue with the external VFO.

Ed

Not sure if the thread is still in circulation.

I had a similar situation with my 530S. Rewound L41 and changed Q1. Although I suspect the original part could have been good. L41 could have been eal culprit. Rewound L41 with inputs from Terry . No 41 wire, 6 turns primary and 26 Secondary. RX is alive but lacks sensitivity. Calibrator signal is rather low. About S7 on most bands but very low (S3) on 1.9 MHz..

I have not yet attempted realignment. Can you throw some light on the Toroidal coil you made ?

Regards

Brian,

The 4PDT relay you referred to which is "RL2". Relay RL2 is located below the chassis, next to the final amplifier circuit/PC board, between the band switch metal shield, the rear panel and is inside a small removable metal enclosure.

Relay RL2 controls:
RL2-1 controls Xverter ground switching of Xverter socket pins 8 and 9
RL2-2 controls Meter switching (from S meter in receive to ALC, IP, HV, and RF in transmit)
RL2-3 control Linear amplifier relays switching using Remote socket pins 1 (ground), 3 (N.C.) or 5 (N.O.) relay terminals
RL2-4 controls antenna change over switching from receive to transmit and vice verse.

The other 4PDT relay, labeled RL1, controls switching of various circuits between receive to transmit and vice verse. You can see relay RL1 by studying the TS-520S high resolution schematic available for downloading at the following link:

http://w5rkl.com/wp-content/uploads/2014/04/TS-520S_LARGE-Schematic_Hi-Res.pdf
http://w5rkl.com/wp-content/uploads/2014/04/TS-520S_LARGE-Schematic_Hi-Res.pdf

You can see the location of both relays in the TS-520S service manual, page 38, Figure 9 for RL2 and Figure 10 for RL1.

Topic: 55469 Message: 55469

Hi folks,

I just read an old qrz.com forum thread that talks about an AM filter MOD for the TS520S.

http://forums.qrz.com/index.php?threads/ts-520-am-filter.454458/
http://forums.qrz.com/index.php?threads/ts-520-am-filter.454458/

It says... "The instructions are from Henry Radio in LA and it tells you how
to modify the CW mode of the TS-520 into AM mode and how to eliminate
the BFO for receiving AM."

I think it involves using an AM filter made for the R599... but not much more.

Does someone in the group know something about this?

Thanks and 73
Guido LU8EQ

Guido,

Modifying a TS-520 to operate AM using CW mode requires adding an "external AM Plate Modulator". The external Plate Modulator is connected in series with the final amplifier's plate AND screen voltages. AM Plate modulation requires that both the final tube screens AND plates be modulated. This will require changing/modifying the Final Unit screen circuit and plate HV.

I personally would not consider modifying a TS-520 to operate AM. The better route would be to purchase a transmitter that is designed to operate AM, no modifications required.

Hi Mike,

Thank you for your kind reply.

I don't think the mod kit was intended for plate modulation. I supposed that it could involve low level modulation and some kind of detector for reception.

I just received a reply from Ted Henry at Henry Radio, saying that they don't have any info left on that kit because it is 40 years old and it was not a high volume product.

The forum post I saw said that it was a kit with a filter and some instructions, so I do not think it was to hard to implement.

I will keep looking for that. If anyone has any info, it will be appreciated.

Thanks and 73

To do the AM conversion, you would also have to add in an AM detector on the receive side in addition to adding the AM filter, besides modifying the audio side of the transmitter to modulate the CW carrier with the low level audio from the SSB generator. Then you would also have to reduce the carrier output to probably no more then 25 watts to keep the 6146's operating parameters in safe territory. Personally, it's not worth the time and effort. If you want to operate AM with a Kenwood rig from that era, find yourself a pair of Kenwood Twins (T-599/R-599 or the T-599A/D-R599A/D). The circuitry of the Twins in some ways was similar to what was used in the TS-520 transceiver. You can also look at the AM board addition and circuitry changes that was used to allow AM on a TS-830S which changed the model number to TS-830M but again, power output is limited to 25 watts.

55475. QRP Circuit - Three Questions

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-09-02 20:37:08 UTC
From: parkave231@...
Topic: 55475 Message: 55475

Hello all! I'm looking into building the "simple" QRP circuit, the one with just the battery and pot. I've tried to find as much info as I can before I attempt to build it, but have a few questions I can't seem to find an answer to.

1. Any suggestions on what kind/type/size of wire to use? (I suppose the part from the pot to the radio would be whatever comes with a DIN pin kit.)

2. It's been a long time since I've read schematics. I see the wire coming from pin 6 to the pot, and then out to the negative terminal of the battery. Does this wire attach from pin 6 to the pot in the middle post, and then out to the battery at the right post (#3)?

With respect to the ground wire, I think this would go from the positive battery terminal to the to the left (#1) post, and I also see the line continuing to the ground pin. Does this mean I need to solder the wire to the post, then solder a second wire which leads from the same post to ground?

3. I've seen some people add an on/off switch. Where would be the best place to stick this in?

I appreciate the input. I'm getting back on the air after quite an extended absence, and there's a lot of things I've sadly forgotten. Back to my ARRL handbook!

73s,

Matt - KE4GXU

Topic: 55381 Message: 55481

I'm a bit late to this thread and am going to be the proverbial wet blanket - having owned both TS-820S and TS-830 over the years:

Go find an R-820/TS-820S combo. Preferably with the unobtanium interconnect cable.

"But it doesn't have WARC!"

Sure they do - if you mod the rigs. QST had a mod article in the early 80s which details how to add the missing bands to your 820 lineup. Given the glut of Coil Pack and VCO/XTAL Boards on the surplus market these days, it's easy to liberate the required coils, capacitors and other components for use in the conversion process. I had to wind my own back in the day...

Neither of my TS-820S were modded to TX on 30M (RX only), as I have other rigs for that band. One got 12M in the AUX band switch spot; the other, 17M. The latter radio uses the 29.5MHz spot for 12M.

All three of my R-820s have been modded so the SWBC Converter works across the entire 10M allocation - not just 29.5MHz. This gives a full 2MHz coverage for each SWBC segment. The Converter crystals were changed to line the various band edges up on 0.0 or 0.5, keeping in line with the TS-820S Het oscillator scheme. This gives me 10 and 18MHz coverage via the Converter in an arrangement which allows full or VFO transceive operation when the units are used together. Two of the three got 12M in the AUX spot and the other got the 11M (25.5MHz) SWBC band added.

Conversion ramblings aside, the R-820 performs as well as my TS-830 did - with knobs suitable for big fingers. Like others in thread, I prefer the 820-series S meter to that of the 530/830. Dual RX and a panadapter (w/ SM-220/BS-8) is a neat tool to have in the vintage lineup.

You may have freq stability issues with the older VFO controlled rigs. I know some of the DIGI modes need dead on stability to be decoded on the other end. My radio is Ham Radio...CW is Real Radio 73, John...K8JD

Greetings group,
I hope we all had a nice Labor Day holiday. I was operating /7 qrp, but propagation was rather poor on both 20 & 40 meters, so I logged only 7 on 20(usb) and 4 on 40(cw).
Now to the subject:
  To those new group members, or those who are moderated: Upon acceptance to the group, you were automatically sent and electronic copy of the group policy/rules regarding posting messages, which also states the group policy regarding signing stated messages/posts. If you are new, or a moderated member, AND your posts/msgs conformed to the established group policy...you posts/msgs have been approved and should have already shown up in the group main msg area. IF they have NOT shown up, then assume that they did NOT meet the criteria. The MOST likely cause of this is: failure to read the group policy regarding properly signing your posts/msgs. The group administration is NOT here 24/7, 365, we do take some time for ourselves and families. So, during major holidays...etc...etc, moderated posts/msgs may take longer than you would like to be read and either approved or rejected by a moderator or co-owner. We strive to do our best...but you just can't please everybody...no matter how hard you try.
We now return you to our regular programming..... 73

Hi Matt,

I don't know which circuit you are looking at but have a look here.
http://www.radiomods.co.nz/kenwood/kenwoodts520.html If you scroll
way down you'll find the QRP mod. They're all the same but this
circuit is pretty clear.

Get a battery snap for your battery, connect the red wire to one end
of the pot and the black wire to the other end of the pot.
Yes you can use a modified din cable (does the plug fit in the socket
at the back of the rig?)
Connect one of the wires from pin 4 of the socket to the end of the
pot with the red wire.
Connect the other wire from pin 6 of the socket to the centre pin of the pot.

The circuit draws microamps from the battery which means you don't
need a switch. However, if you're worried about battery drain you
could pull the snap off the battery or put a switch in line with
either the red or black wire on the battery snap.

Hi Pete,

Thanks for the tips. I was not aware of the existence of a TS-830M. I've checked the block diagram on that rig's manual and there is not too much to implement... but it could be demanding.

Thanks again.

To do the AM conversion, you would also have
to add in an AM detector on the receive side in addition to
adding the AM filter, besides modifying the audio side of
the transmitter to modulate the CW carrier with the low
level audio from the SSB generator. Then you would also have
to reduce the carrier output to probably no more then 25
watts to keep the 6146's operating parameters in safe
territory. Personally, it's not worth the time and
effort. If you want to operate AM with a Kenwood rig from
that era, find yourself a pair of Kenwood Twins (T-599/R-599
or the T-599A/D-R599A/D). The circuitry of the Twins in some
ways was similar to what was used in the TS-520 transceiver.
You can also look at the AM board addition and circuitry
changes that was used to allow AM on a TS-830S which changed
the model number to TS-830M but again, power output is
limited to 25 watts.Pete, wa2cwa

TS-520_820_530_830@yahoogroups.com, <w5rkl@...> wrote
:

Guido,

Modifying a TS-520 to operate AM using CW mode requires
adding an
"external AM Plate Modulator". The external Plate
Modulator is
connected in series with the final amplifier's plate AND
screen
voltages. AM Plate modulation requires that both the final
tube
screens AND plates be modulated. This will require
changing/modifying the Final Unit screen circuit and plate
HV.

I personally would not consider modifying a TS-520 to
operate AM.
The better route would be to purchase a transmitter that is
designed
to operate AM, no modifications required.

Yes, this is very do-able. I've done this with no problems with my TS520. Hints:

1. TURN DOWN THE POWER! You only need, at most, 5 watts to get out on JT65 (any more is too much!) You can work the world on 5 watts or much less. I do this by turning down the microphone input to as low a level as possible.

2. Tune around with the waterfall. With the 520, I have no frequency display, so look at your software waterfall to put yourself in the right range for JT65 signals. On 20m at 14.076 USB I usually have to turn the dial around a bit to find where everyone is.

3. Warm up the rig beforehand... trying to operate JT65 when your VFO is still stabilizing is dicey, as there is some warmup drift, for sure.

Anyway, not much to it aside from making sure the power levels are appropriate.

Good luck!

I haven't seen any frequency stability issues, at least with my TS520 -- when it's warmed up for a few minutes, that is. Each pass on JT65 is exactly one minute long, and it's pretty tolerant of signal condition changes etc.

Trying to run JT65 on a Swan 350 might be another thing, but all of my Hybrid Kenwoods are stable enough when warm to work digital no problem. (I do see a bit of crystal filter leakage and DSB signals on PSK31 on my TS520, but only with nearby, local stations...)

Ben,

Turning down the power with the mic gain is the WRONG way to lower the power. The power should be reduced by applying a negative ALC voltage on the back of the rig. That topic has been discussed here many times. Most people use a 9v battery with the negative lead tied to the center of a pot, with the positive lead to ground. This will apply a variable negative voltage to the ALC line, reducing the output power of your radio without detuning it.

Ben and all, YES the TS520 has a good frequency readout if you calibrate it properly ! It is the analog dial. With the circular markings you can be sure within 0.5 KHz of your frequency. Anything closer that is just nit-picking and not really necessary unless you are within a hair of a band edge.The procedure to set the dial is in the user manual ! Trimming the Xtal calibrator is a good idea if you never have done it, turn on the calibrator and zero the cal trimmer cap against WWV !
I hate this prejudice against analog. We never had any digital readouts for the first 75 years of Ham radio ! My radio is Ham Radio...CW is Real Radio 73, John...K8JD

There is no transformer supplying the 5vdc regulator. I suspect you are looking at the Pi-Filter Choke that is mounted below the aluminum heat sink?

14 vdc is fed to the 3 terminal regulator mounted on the aluminum heatsink. Very common for the heatsink to have a lot of motion due to loose mounting screws and/or loose brass standoffs.

Suggest you remove the two screws that hold the heatsink to the standoffs and use a nut driver to tighten the standoffs and then remount the heatsink.

Before you do that look at the leads from the 3 terminal device to make sure they are not very long protruding from the PC board solder joints. Not uncommon for them to extend too far out and make contact with the grounded metal shell of the power transformer. Not unusual to find that an owner has placed black plastic electrical tape or piece of cardboard between the 3 terminal regulator leads and the metal shell of the transformer to prevent this shorting.

Guido:

What you are seeing in the TS830M AM board schematic in the TS830S documentation is only the receiver mod for detecting am. You need to study the TS830M schematics to understand the mod you need to make for transmitter AM modulation. That mod involves rewiring the S18 Mode switch.

The 830M S18 mode switch does away with the CW-N position as a 6khz filter is in that position and replaces it the CW-N with USB and then LSB is where USB would have been wired and the AM position is where LSB would have been wired. They add diode D11 to S18 deck 5. When mode switch is placed in AM position D11 is forward biased and applies 9vdc to the SSB pin on Molex Conn 9 on the IF board. That 9vdc biases on transistor switch Q38 which turns on Mic amps Q19 and Q20. Now with Mic amps enabled in CW mode you can modulate the carrier.

With the mode switch in AM mode you are really in CW Mode with the CAR Level pot enabled and with the Mic amps enabled. After loading normally in CW mode to approx 100 watts out @225ma you then place Mode switch to AM and advance the CAR pot for no more than 130ma Ip and then speak in Mic and advance the Mic gain until you just see some flicks of ALC on voice peaks.

There is no screen grid and/or anode modulation going on with KW 6146 tetrodes. They are modulating the carrier at the output of the BM. So a modulated TIF signal is applied to the TX Mixer on the RF board.

Of course these mods could be made to a TS830S, but as some have suggested a lot of work for little gain. Not sure about availability of boat anchor transmitters for you? Heath DX-100 and Johnson Viking used plate modulation and many of the lower power transmitters like Heath DX-40 and DX-60 used low level modulation by varying screen grid voltage. The Globe Scouts sold by World Radio Labs used Heising modulation. Been a very long time ago when I owned and operated these old rigs on AM.

Lastly, dont forget the old tube CB base radios can be pretty easily put on 29.000mhz and have fun there with low power AM.

Hello Terry,

Thank you very much for your kind email.

The mod I was wondering about is intended for a TS520S, using the cw optional filter position with a broader one for AM.

I know the power output will not be great, but I really enjoy the TS520S sound (both tx and rx) and wondered about how would it sound on AM.

It is very hard to find vintage equipment for AM here in Argentina. There are a lot of folks using pwm modulation homebrewed rigs, and of course, tube based monsters (also homebrewed) with several tubes using huge modulation transformers for hifi AM and such.

I will start writing some notes regarding the steps needed to perform the modification, carefully looking at the rig's schematics and go slow, step by step. I think making it receive proper AM would be the first one.

Thanks again for your words.

OK-----Was trying to tell you that using the AM detector that the TS830M uses isnt the only thing you would need to do.

Unlike the TS830S the TS520 mic amp transistors are on all the time with the audio output to the BM opened in Tune and CW using the S3 mode switch contacts. So will need to get mic audio to the BM input in CW mode assuming your plan is to use same low level modulation method.

Might look at the Yeasu FT series schematics to see how they do it.

John,

I 100% agree with you on the analog dial -- my analog dial is calibrated very well, thank you. But with the digital stuff you sometimes have to be closer than 0.5 kHz to match a signal. No prejudice here, I love the analog dial and the TS-520. But you do need to use the waterfall to be spot on. (ie for PSK31, I tune to 14.070... but you might have to shift left or right ever so slightly to get the software waterfall just right).

Nothing bugs me more than when some ham complains that I am at "14.265.0006" and not "14.265.0000"... That said, I'm also happy to call CQ on any frequency (hey, we're not channelized on most of our bands, so why the obsession with round 0's?).

(Also on all the folks on the proper way to turn down power using 9V and ALC -- yes, aware of it, and using it. However, for someone just trying to get on the air with digital without having to pull out their 9V battery and putting together a circuit, can at least try it out with the mic pot.)

Hi Rodger,

Thanks for your message.

The audio mods on that page are great. I've done those to my ts520s and it sounds great. The AM mod proposed there uses the rig in ssb mode bypassing the filter... it is prone to ultrawide tx (no so great to others in the air next to your frequency)... I already have the 6KHz filter so I will use it in the CW optional filter position... Also I would like to add a detector to receive AM too.

Thanks Terry for all suggestions,

I am now focusing on Aligning ANT and RX Coils I can not touch 1.5 ANT Coil L41, which is rewound and is far too fragile now for any adjustment. Any attempt to tune it will surely snap the delicate No. 42 wire. Calibrator signal on 1.5, 3.5 and 10.1 MHz is very poor. Is OK on all other bands. It is S 7 on both 7 and 14 MHz. When I compare it with my TS-590SG, it is lower by 2 S Units. Signals which are S9 on 590 are S7 on 530S. And this is not an S Meter issue.
This does call for realignment, but I am intimidated by the very thought of putting a screwdriver inside the radio. I use the radio every day on 7 and 14 MHz CW/SSB and extremely happy with it's performance, barring slightly poor receive. Just a short note to thank you gentlemen for all your help and support. 73

Rahul:

There is one other thing you can check. Sometimes (not often) D2 protection diode shorts and loads down the secondary of L41 step up transformer. D2 is a protection diode that is turned on when there is Driver tube cathode current. It protects Q1 RF amp Gate 1 from the rigs internally generated transmit RF. When D2 is biased on it shunts any RF signal at Gate 1 to ground. It gets its forward bias from the IR drop across R35 150 ohm.

With rig down powered measure the resistance of R35. It is near the Driver tube and vertically oriented so can get on the top hair pin loop. Should measure close to 150 ohms. If it measures around 114 ohms then D2 is shorted. 114 ohms is the parallel combination of R35 and R27 (ohms law!). You can also just cut the hair pin loop of D2 with mini-dykes and watch the S meter to see if signal levels come up.

Usually when D2 is shorted the bands from 18 mhz and up are more effected. Also L41 peak at 1.9 mhz will occur with the slug core backed out 2 or 3 threads from the top of the shield can (for a factory original winding) as opposed to the peak occuring with core flush with top of shield can. Also the ANT coil slugs will have to be driven deeper into the formers with 21mhz nearly bottomed to get any kind of peak with Drive control at 1200.

You can also test D2 by injecting weak signal at SO-239 or if no RF sig gen then use the Marker. While watching the S meter connect 3vdc supply negative to chassis and touch positive lead to top hair pin loop of R35. If no bench supply use couple of 1.5vdc batteries in series. When you touch positive lead to R35 will forward bias D2 and it will turn on hard and shunt RF signal to ground at Gate 1 of Q1 RF amp and S meter will drop and volume in speaker lower.

D2 is a 1S2588 band switching diode. It is hard to find. I replace bad ones with a 1N4148. Not exactly the same but will work. Band switching diodes work just like a mechanical set of switch contacts. When open (off) present a very high impedance and when closed (on) present a very low impedance. Want High Z when D2 is off so not dragging down Gate 1 of Q1. Dont replace with a Vari-cap diode as some will tell you. 1S2588 is not a Vari-cap and no need for a Vari cap in this circuit. Just want fast turn when cathode current flows in 12BY7A Driver tube.

Lastly if D2 is shorted you can cut its top loop in center and spread the ends and tack solder a 1N4148 diode to the stub leads Cathode lead to ground. I dont like to make PC board top side repairs like this, but this would save you from pulling the RF board again.

Thanks Terry

D2 does not appear to be short. Its the lower two bands 80 and 160 that are suffering from poor sensitivity. If D2 was shorted the RX would be very poor.
On 40 and 20 the Signals are just One S Unit shy of what it should be, S9. L41 might require realignment on 1.8 Mhz because this coil has been rewound and on 1.8 this IS a tuned circuit. L 13 MIX coils might require realignment because Q1 was changed. Although it is replaced with same FET 3SK73. Now sensitivity on 1.8 can be touche up by ONLY L 13. I do not know if that is so critical because it appears to be a low Q coil as it has been shunted with a low value resistor.
I know its not as daunting a job, but I fear the risk of breaking a core on this otherwise outstanding radio. In terms on RX and Transmit audio, it beats my brand new TS590SG hands down.

Maybe I will fashion a home made plastic alignment tool and try it on a Sunday morning. Wouldnt like to fiddle with any metal screwdriver.

Kind Regards Terry

David Kuraner, K2DK, had an article on AM conversion of the Heathkit HW-100 in Electric Radio edition 211 December 2006, page 16 "THE HEATHKIT HW-100 AM TRANSCEIVER". He describes the problems associated with converting a vacuum tube side band transceivers for AM. He also referenced /Bill Bowie WC3K (SK)/ Electric Radio article covering modification of a Heathkit SB-401 transmitter for Carrier Controlled AM mode (Electric Radio edition 139 December 2000).

Although the above Electric Radio articles cover modifying vacuum tube side band transceivers/transmitters for AM operation, they give ideas and problems the author's experienced associated with modifying a side band transmitter/transceiver for AM operation.

The Kenwood TS-520 uses the same 3.395Mhz IF frequency as the Heathkit HW-100, HW-101, SB-100, SB-101, SB-102, SB-400 and SB-401 line of transceivers and transmitters. Will the TS-520 AM filter work in one of the Heathkit side band/CW transceivers or transmitters? I have no idea.

55511. Contact Cleaning

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-09-13 02:43:16 UTC
From: w5rkl@...
Topic: 55511 Message: 55511

I came across a discussion on another Yahoo Ham Group about Deoxit contact cleaner and whether it was "conductive" or not.

The following was taken from Craig Laboratory INC website:

http://store.caig.com/s.nl/ctype.KB/it.I/id.703/KB.215/.f
http://store.caig.com/s.nl/ctype.KB/it.I/id.703/KB.215/.f

concerning Deoxit contact cleaner, D5 and F5 Fader Lubricant as being conductive.

Are DeoxIT® Products Conductive?
I recently read on the Boatanchors Mail List (restoration of vintage radio gear) a claim that DeoxIT® is "conductive." It stated that "The DeoxIT® caused a short on the phenolic wafer switch between a connecting tab carrying 175V plate supply to the bandswitch AND the mounting screw which is grounded."

Please provide any information concerning the role that solder flux may have played; along with the necessary specifications and applications information for using DeoxIT® on live electrical circuits or circuits that are energized after application.

Thank you,

A. Allen
Audio Service
.....

DeoxIT® is NOT conductive, however, phenolic is composed of multiple layers of material and readily absorbs liquid. As a result, any product that contains a conductive material should not be used. Most manufactures include alcohol in their contact cleaners, lubricants and preservatives (even very small percentages), and alcohol will cause short circuits.

DeoxIT®, DeoxIT® GOLD, DeoxIT® SHIELD, DeoxIT® FaderLube liquids are completely non-conductive, and neither the 100% liquids or the 5% spray versions contain alcohol or any other conductive constituents.

Warnings should be issued cautioning technicians from using any contact cleaners containing alcohol. This is one of the most common misuses of contact cleaners.

Also, the use of silicone in any type of contact cleaning solutions should be avoided because it can be detrimental to the long-term performance of the contact or switch because it will degrade phenolics and plastics over time.

DeoxIT ® is used for many applications including telephone switching systems that contain phenolic materials. Care should be taken to reduce exposure of any materials, including DeoxIT ® to phenolic materials due to its porosity.

Even superior phenolics over long periods of time degrade, and thereby more easily absorb any materials, whether it be DeoxIT ® or any other product. To prevent this from happening, we offer many applicators to assist the technician in applying our products to the metal surfaces directly without concern with over-spray on to the phenolic materials.

If a spray version is required due to inaccessibility of a contact area, we recommend our DeoxIT ® (D100S-2) 100% spray, which contains no solvent. This version reduces potential over-spray by confining the product to a controlled area without migration of solvent.

The DeoxIT ® 100% solution is safe for use on energized circuits, as is our new non-flammable DeoxIT ® DN5 (DN5MS-15) spray.

Our most popular DeoxIT ® D5 (D5S-6; flush - slow dry) is not recommended for energized circuits due to the fact that it contains a flammable solvent. We always recommend turning equipment off prior to application, and waiting two minutes before turning the equipment back on.

This caution is due to the brief flammability of the solvent, not the conductivity of the solvent. If the energized system arcs, it could cause a flash, thus causing damage to relay contacts, power contacts, commutators, etc.

Finally, DeoxIT ® spray is not recommended for rosin flux removal.

Notice the mentioning use of Alchhol in other contact cleaners and how it can, if used as a contact cleaner, cause a short. I have read where some hams use only Alcohol to clean switches and pots.

I have never experienced damage to any Phenolic wafer switch when using DeoXit D5 as a contact cleaner. After the cleaning is complete I use generous amounts of canned air to remove any residual cleaner from the wafer switch and surrounding contacts to significantly reduce the chance of the Phenolic wafer absorbing the cleaner.

I've had several request for more hybrid cabinet paint. Here is the story.....

Several years ago I needed paint so I ended up going to a local paint company to have them mix some up. The procedure is that I have to purchase 1 quart, which they then put into spray cans. The quart makes up between 11 & 12 cans. Since I only need 2 cans, I will sell the remaining for cost plus shipping. The last time the cost came out to $13 plus shipping cost via Parcel Post. The can's have to ship by land, thus Parcel post.

I suspect the cost will be the same, but I won't know for sure until I pick the paint up in a day or two.

So what I ask is that anyone needing paint, email me. Last time in order to fill all the request I had to order around 50 can's, as I recall. I would be willing to do this again as long as I don't get stuck with more than the 2 cans that I need.

I picked up the paint and the price will remain the same as the previous order was several years ago at $15 plus shipping via parcel post.

So far 3 out of the 10 can's have been spoken for.

73's,
Mark, WB0IQK

Sorry about this. The price will remain the same at $13 plus shipping, not the $15 that I indicated in the post.

I sold the same paint several years ago on ebay for $15.

Mark, WB0IQK

Mike,
Thanks for this information. This is quite interesting. When I got into working on old vintage radios a couple years ago the common method for cleaning band switches that I learned from many radio restorers on YouTube was to use 90% isopropyl (rubbing) alcohol on a q-tip, this is obviously a bad idea and I won't be doing it again. This is very commonly recommend by many people I follow on YouTube.
Although I do use deoxit too, I have many times used the alcohol first to clean what appeared be visible old grime from years of use then went back over that with deoxit afterwards, not any more.

Tom,
Yes there are some Youtube videos showing cleaning of switches. I have my own method of cleaning wafer switches. I use old tooth brush wet with cleaner then gently scrub the switch clean. I follow that with generous amounts of canned air to remove any residual cleaner on the switch or surrounding components or PC boards. I have used that procedure for at least 5 years and never experienced wafer switch failure, whether within a week, month or even a year later as some hams seem to have experienced. I have used that procedure on Heathkit, Kenwood, Johnson, and Hallicrafters receivers, transmitters, transceivers, VTVMs, and modified CB radios on 10 meters and none of them have ever had a set of relay contact, phenolic wafer switch, pot, phenolic tube sockets, LMO/VFO variable capacitor flex shaft to frame connection, or other failure due to using DeoXit D5 or F5 Fader cleaner lubricant.

I don't know what procedure those hams who have experienced failures, are using. I can only guess that they are not including the use of canned or compressed air to remove the remaining cleaner after the cleaning process has been completed, at least none of them have ever said they use air to remove the remaining cleaner.
I have never used Alcohol to clean switches, pots, or other electrical contacts. I have used WD40 as a lubricant on the tab washers on a TRW LMO in Heathkit SB-300, SB-100, SB-101, SB-400, and SB-401 receiver, transceivers, and transmitters. I apply WD40 to the washers using a cotton swab wet with WD40 then press down on the washers which squeezes the WD40 from the cotton swab so it seeps down between the tab washers. I use just enough to do the job and I check to ensure that the WD40 does not 'drip" from the washer.
To each his/her own I guess. I just know my procedure works well for me and has been now going over 5 years.

The following was taken from Craig Laboratory INC website:

http://store.caig.com/s.nl/ ctype.KB/it.I/id.703/KB.215/.f
concerning Deoxit contact cleaner, D5 and F5 Fader Lubricant as being conductive.

Are DeoxIT® Products Conductive?I recently read on the Boatanchors Mail List (restoration of vintage radio gear) a claim that DeoxIT® is "conductive." It stated that "The DeoxIT® caused a short on the phenolic wafer switch between a connecting tab carrying 175V plate supply to the bandswitch AND the mounting screw which is grounded."

Please provide any information concerning the role that solder flux may have played; along with the necessary specifications and applications information for using DeoxIT® on live electrical circuits or circuits that are energized after application.

Thank you,

A. Allen
Audio Service
.....

DeoxIT® is NOT conductive, however, phenolic is composed of multiple layers of material and readily absorbs liquid. As a result, any product that contains a conductive material should not be used. Most manufactures include alcohol in their contact cleaners, lubricants and preservatives (even very small percentages), and alcohol will cause short circuits.

DeoxIT®, DeoxIT® GOLD, DeoxIT® SHIELD, DeoxIT® FaderLube liquids are completely non-conductive, and neither the 100% liquids or the 5% spray versions contain alcohol or any other conductive constituents.

Warnings should be issued cautioning technicians from using any contact cleaners containing alcohol. This is one of the most common misuses of contact cleaners.

Also, the use of silicone in any type of contact cleaning solutions should be avoided because it can be detrimental to the long-term performance of the contact or switch because it will degrade phenolics and plastics over time.

DeoxIT ® is used for many applications including telephone switching systems that contain phenolic materials. Care should be taken to reduce exposure of any materials, including DeoxIT ® to phenolic materials due to its porosity.

Even superior phenolics over long periods of time degrade, and thereby more easily absorb any materials, whether it be DeoxIT ® or any other product. To prevent this from happening, we offer many applicators to assist the technician in applying our products to the metal surfaces directly without concern with over-spray on to the phenolic materials.

If a spray version is required due to inaccessibility of a contact area, we recommend our DeoxIT ® (D100S-2) 100% spray, which contains no solvent. This version reduces potential over-spray by confining the product to a controlled area without migration of solvent.

The DeoxIT ® 100% solution is safe for use on energized circuits, as is our new non-flammable DeoxIT ® DN5 (DN5MS-15) spray.

Our most popular DeoxIT ® D5 (D5S-6; flush - slow dry) is not recommended for energized circuits due to the fact that it contains a flammable solvent. We always recommend turning

equipment off prior to application, and waiting two minutes before turning the equipment back on.

This caution is due to the brief flammability of the solvent, not the conductivity of the solvent. If the energized system arcs, it could cause a flash, thus causing damage to relay contacts, power contacts, commutators, etc.

Finally, DeoxIT ® spray is not recommended for rosin flux removal.

Notice the mentioning use of Alchhol in other contact cleaners and how it can, if used as a contact cleaner, cause a short. I have read where some hams use only Alcohol to clean switches and pots.
I have never experienced damage to any Phenolic wafer switch when using DeoXit D5 as a contact cleaner. Sorry about this. The price will remain the same at $13 plus
shipping, not the $15 that I indicated in the post.

I sold the same paint several years ago on ebay for $15.

Topic: 55511 Message: 55522

Tom,

I can second W5RKL's method. I have been using WD40 to clean switch contacts for years and have had fantastic results. My TS520S was barely working when I bought it about 3 years ago, all it needed was a thorough clean of all the switch wafers with WD40,and it has never missed a beat since.

I have also used it on a TS940 - removed every cable connector, sprayed with WD40 before re-connecting, and I am amazed at how much better that radio works - this was about a year ago and hasn't missed a beat since. I even dismantled the miniature relays in the attenuator and cleaned them with fine wd40 soaked paper - I have since purchased a new relay but it is still sitting in my parts drawer as the original one is now working so well!

Do not use alcohol - it is a very powerful solvent and will slowly dissolve most paints, and many types of plastic. I hate to think what it will do to the phenolic wafer material over time. It also completely evaporates off the contacts and does not leave a protective film to stop corrosion as WD40 or De-Oxit does.

Cheers,
Peter - VK2AN

55523. Need Send/Receive Lever for TS-820S

Yahoo group: TS-520_820_530_830 (2015 — 2016)

I acquired a non-working TS-820S that I would like to restore.

On this one the plastic lever on the send receive switch is missing, although the switch works fine when you move it with your finger.

Were the plastic levers removable, or do I need a whole new switch?

Does anyone have one in their junk box?

Thanks,

Craig

Craig,

These levers are one of the few "wonky" things on an 820S! The levers are removable, but you have to take off the front panel to do it. I was able to (sort of) repair one of mine that failed (send/receive also-it gets lots of use). If you can repair it, put the repaired one in a less-used position (MONI, maybe) and put the more robust one on S/R. There was a guy on ebay that was selling these for quite a while, but I thought he disappeared having sold all his stock. Worth a look though, and others may be aware of other sources. Also, try Walter Dilley, who is a great source for vintage Kenwood stuff (I forget his call-search on his name on this board and you'll find him or he may respond to these notes).

Good luck & 73

Dave K3DWB

Interesting.... My Send/receive switch is the first thing that broke on my TS520. It sits near the edge of the front panel and when I was moving it I bumped it on something and SNAP it came off. I was not using it for anything since the few times I got on fone the P T T button on the mic did that job and on my CW operation I switched on VOX and the first dit on the key activates the transmitter and the delay holds the transmitter on until I pause or stop sending CW ! So I never made much effort to replace the lever on that switch !Have fun taking that @#%&* front panel off, It's a Bear of a job ! My radio is Ham Radio...CW is Real Radio 73, John...K8JD

55531. Hybrid Net Update (September 18, 2016)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-09-18 19:30:11 UTC
From: Mark Gilger
Topic: 55531 Message: 55531

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by me, WB0IQK. There
were 25 stations checking in under good band
conditions. The net was terminated early due to a thunderstorm in my area.

We had the following number of radios checking in.

4 running TS-520(x)
2 running TS-530(x)
2 running TS-820(x)
5 running TS-830S
0 running TS-510
0 running TS-511
0 running TS-515
0 running 599 twins
0 running TS-900

I was running my TS-830s + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
14 stations checking in fairly good band conditions.

We had the following number of radios checking in.

1 running TS-520(x)
1 running TS-530(x)
0 running TS-820(x)
4 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830s + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 ☐ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins

November 2015, Saturday net total = 66, Sunday total = 46
December 2015, Saturday net total = 55, Sunday total = 73
January 2016, Saturday net total = 129, Sunday total = 81
February 2016, Saturday net total = 98, Sunday total = 72
March 2016, Saturday net total = 74, Sunday total = 35
April 2016, Saturday net total = 101, Sunday total = 57
May 2016, Saturday net total = 51, Sunday total = 32
June 2016, Saturday net total = 39, Sunday total = 46
July 2016, Saturday net total = 52, Sunday total = 54
August 2016, Saturday net total = 28, Sunday total = 35
September 2016, Saturday net total = 41, Sunday total = 25 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Update on TS 530S L41

Yesterday aligned ANT and RF(MIX) Coils In absence of proper non-metallic alignment tool, used a small precision metallic screwdriver. Not a good idea. Did NOT touch L41 and L13, the two 1.5 MHz Coils. Started with 3.5 MHz Coils. On Ant Coil, the slug had to be moved OUT two turns. The RF Mix Coil there was absolutely no change. This is quite amazing as the radio has never been touched ever since it was made. Progressively Aligned other bands. But in ALL cases the MIX coil was perfect. No change was needed. And Ant coil had to be moved out a turn or two.

Freq S Meter Calibrator Signal Before alignment S Meter Calibrator Signal After Alignment Change 1.900 3 3 0 3.700 6 8 2 7.100 9 9 0 10.150 3 7 4 14.175 7 8 1 18.150 7 8 1 21.250 8 8 0 24.750 9 9 0 28.500 8 8 0

Mode CW DRV @12 Car Full

So Max improvement was on 10 MHz followed by 3.5. On 20 and 40 Change does not appear so much, but significant improvement in low signals reception. The One Odd S meter change from S7 to S8 shows significantly and now the Noise level has risen to S4-5, at par with my TS590SG.

Special mention of Terry K9TW without whose valuable support this precious radio would have gone to trash. I just love this 530 now. As for 1.5 MHz I am not willing to touch L41 now till I have some back-up plan in hand. No activity on 1.8 MHz in my part of the world anyway.

Rahul,
As previously mentioned on several occasions do not use a metallic driver, you are lucky not to have broken or cracked any slugs. Using a metallic driver will give you an inaccurate indication when tuning. It is also advisable to make several sweeps of the alignment procedure. You'd be surprised how much difference it may make.
As for alignment tools you can file down a plastic knitting needle or a piece of wood. These are only suggestions to assist you when proper tools are not available.

Good job on your achievement

Dave,

Thanks fore your comments. I absolutely agree on Alignment Wand. Although I used minimum force, ensuring no damage to cores, but as you point out, it gives erroneous readings. Will make a small plastic or wooden wand here and redo alignment. But not expecting much change now. The bands still low are 1.5 and 10 MHz. I guess this may have something to do with Quality of my rebuild on L41.

Thanks again Dave

Rahul,

Don't sell yourself short, if you are not proficient at radio repairs/alignments, then it takes time. Whilst you have great concern for L41, there are other factors that you should consider. Personally, I wouldn't attempt to rewind L41 as my hands and fingers are no longer steady enough for such fine Angel Hair wire. But I would suggest that you would see improvement on bands that around 6dB low. With gentle alignment you'd be surprised just how much you can obtain. But again you have to practice. Every radio that comes across my bench, get a full alignment, this means going through the coil pack alignment 3-4 times. I always allow the radio and test equipment to warm up for at least an hour. Some will say over the top, but I have time and always have had great success. Remember one man's failure is another man's success.

I would suggest seeing your an owner of the hybrid radio, to monitor this forum, for all of the different models, you'll be surprised just how much you can learn from the emails.

Dave,

Thanks fore your comments. I absolutely agree on Alignment Wand. Although I used minimum force, ensuring no damage to cores, but as you point out, it gives erroneous readings. Will make a small plastic or wooden wand here and redo alignment. But not expecting much change now. The bands still low are 1.5 and 10 MHz. I guess this may have something to do with Quality of my rebuild on L41.

Thanks again Dave

Rahul,
As previously mentioned on several occasions do not use a metallic driver, you are lucky

not to have broken or cracked any slugs. Using a metallic driver will give you an inaccurate indication when tuning. It is also advisable to make several sweeps of the alignment procedure. You'd be surprised how much difference it may make.
As for alignment tools you can file down a plastic knitting needle or a piece of wood. These are only suggestions to assist you when proper tools are not available.

Good job on your achievement

"yellow_kite@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Update on TS 530S L41

1. Yesterday aligned ANT and RF(MIX) Coils
2. In absence of proper non-metallic alignment tool, used a small precision metallic screwdriver. Not a good idea.
3. Did NOT touch L41 and L13, the two 1.5 MHz Coils.
4. Started with 3.5 MHz Coils. On Ant Coil, the slug had to be moved OUT two turns. The RF Mix Coil there was absolutely no change. This is quite amazing as the radio has never been touched ever since it was made.
5. Progressively Aligned other bands. But in ALL cases the MIX coil was perfect. No change was needed. And Ant coil had to be moved out a turn or two.

Freq S Meter Calibrator Signal Before alignment S Meter Calibrator Signal After Alignment Change
1.900 3 3 0
3.700 6 8 2
7.100 9 9 0
10.150 3 7 4
14.175 7 8 1
18.150 7 8 1
21.250 8 8 0
24.750 9 9 0
28.500 8 8 0

Mode CW DRV @12 Car Full

So Max improvement was on 10 MHz followed by 3.5. On 20 and 40 Change does not appear so much, but significant improvement in low signals reception. The One Odd S meter change from S7 to S8 shows significantly and now the Noise level has risen to S4-5, at par with my TS590SG.

Special mention of Terry K9TW without whose valuable support this precious radio would have gone to trash. I just love this 530 now. As for 1.5 MHz I am not willing to touch L41 now till I have some back-up plan in hand. No activity on 1.8 MHz in my part of the world anyway.

Rahul:

I told you how to test L41 in circuit couple of times. Can do this without touching L41.

Do you have a RF signal source? Do you have a means to measure low level RF voltage? Here is procedure:
1. Rig downpowered.
2. Band switch at 1.5
3. Drive control at 1200
4. Connect RF sig gen hot lead to TP-1 on RF board and ground lead to one of the vertical board metal shields.
5. Connect RF voltage measuring instrument (RF millivolt meter or O-scope) to the "S" solder lead on VC-1 air variable capacitor (lug connected to small set of plates). Note: Can use RF probe and VTVM or DMM , but need higher injection level to overcome diode junction.
6. Set RF sig gen to 1.9mhz
7. Inject 5mv or -33dBm into TP-1.
8. Vary the RF sig gen frequency around 1.9 mhz for a peak on the O-scope or RF millivolt meter. Peak should occur close to 1.88 to 1.9 mhz. Peak the voltage at "S" with the Drive control. RF voltage should peak very close to 1200.
9. With 5mv injected should see close to 37mv at "S". Voltage ratio will be approx 7:1 to 8:1. Yes L41 has approx 4:1 step-up ratio, but your RF sig gen is not terminated in 50 ohms so you will see approx 2x or 8:1 instead of 4:1.

If you cannot measure that low a input level then try it at higher level. O dBm or 224 mv will work, but always better to use low level signal. In operation L41 sees off air signals in uv levels.

You can use a germanium signal diode (1 diode) RF probe and VTVM or DMM as your detector, but will need high level of RF input to overcome the diode barrier (200mv to 300mv). For example if you inject 50mv or -13dBm you should see approx 275 to 300 mv on the DMM.

If you see a 7:1 or 8:1 voltage step up at around 1.8mhz to 1.9mhz with Drive control at 1200 then you know your rewind is good. Normal slug/core position for a factory L41 would be near flush with top of the shield can. If your slug position is markedly different for max voltage step-up then you know you have changed the inductance when you rewound it. If you are within plus or minus 1 or 2 threads you are good.

Hey Bill,

There is a TS430 Group where this problem might have been addressed. Join and type your problem in to look over past similar queries.

I had a low power problem with a 430, it's common to the rig and it's in the PA board. There is a video by N4DA you can check out that shows the fix you can do, but first eliminate power supply problems, connection cord intermittents, etc.

Good Luck.

Bill,

I'm sure you'll get a lot of emails about this being the wrong group (the 430S not being a hybrid!). That said, I have been debugging a TS-430S with the same symptom for the last couple of weeks -- on air light goes on and stays on. In my case, it's sometimes intermittent. I would check: 1. wire to send/receive button on the case can get pinched up against the case if it was not assembled properly and cause transmission when it shorts to the case (one of multiple issues with my rig); 2. corrosion or problems with send/receive button, causing it to stick on (also saw this one -- downside of a radio which installed on a boat on the ocean!); 3. check all connectors for bad solder joints or loose/corroded connections. 4. Check VOX switch and all connections -- mine, for example, had salt corrosion in the switch, causing it to trigger PTT if in the full break in position. 5. VOX circuit and electrolytics, connections... Probably other stuff to check, I'm just diving into mine. Anyway, lots of stuff in the PTT path for the 430S -- follow the schematic--but I'd check mechanical stuff first.

ps. Apologies to the group for the reply to the group, would have emailed Bill privately if Yahoo let me!

Good luck!

I am well aware of what year that the "hack" took place...but yahoo did not widely disseminate THAT info AND started telling you to change your password, until "Verizon" was going to buy them. It seems that all the giant entities will try and hide, for as long as possible, any information compromise, as it really upsets their bottom line...when people with more money than me or you combined...are involved.
My post to the group was for protection of the members

55544. LOW/NO Output on two bands

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-09-23 21:53:18 UTC
From: k1hh@...
Topic: 55544 Message: 55544

Hello Group:

I have a new to me TS0520se that I picked up for use on our Florida Vintage SSB Net, which we call AFLLLAC because SOME of the old radios sound like ducks. I'm proud to say the TS-520se sounds great. I've even checked in the Hybrid Net on 20M on Sunday. Here's my problem.

The unit shows good Drive levels on all bands 160-10M. It has good RF out on 40-10 meters. It has NO RF transmit out on 160M and has varying amounts of RF out on 80M. Its strange on 80. At the LOW end of the band, say 3.5 to 3.65 it has maybe 80 watts out, but 3.65 up to 4.0 the RF output drops to 30-40 watts.

I have not done any alignments, I have cleaned the bandswitch with Deoxit, HV appears good, radio receives well. I have read the excellent article online from the "hybridstore" about possible final cage problems.

Any suggestions from the assembled membership of this forum is appreciated. I suffer from "essential tremor" (nothing essential about it to me) of my hands and don't want to start chopping without a plan.

Thanks in advance,
Rodger K1HH

55545. TS-530 band selection question

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-09-23 17:16:54 UTC
From: royaldragonusa@...
Topic: 55545 Message: 55545

My TS-530sp has an interesting, and odd anomaly that I am curious about.

Each band has a frequency from the bottom of that band on the band switch (80, is marked as 3.5mhz, 40, as 7mhz for example). There are two odd ones though. The AUX is the obvious one, and I think we figured out that it is for overseas 11 meter use. Someone pointed out there are missing components inside, that if installed would make the rig function on 11 meters in the AUX position. So that question is settled.

However, there is one more oddity I have yet to see anyone talk about. On the other side of the scale, you have a 1.5mhz marking...which is in the middle of the AM broadcast band (start of the extended AM I believe). My rig puts out about 1 watt on 1.555mhz, and 18 watts on 1.600. So I can transmit and receive on it if I really wanted to break the rules.

Now, I clearly see this the setting is for 160 meters. So I am wondering, why was it not marked as 1.8mhz?

Is not 1.5mhz something like 200 meters, or at least 180? I have always seen this billed as a 10 thru 160 meter rig, but it clearly goes way further down than that.

Was 200 thru 180 meters originally HAM bands before the extended AM came to be?

Was it originally sold as a 10-180 or even 10-200 meter rig?

Are these bands open to use in other parts of the world, but not in the US?

Whats the story behind this little oddity?

Hi Gian,

The 1.5 on your band selector for 160 meters is normal. Add your vfo frequency to that. For example, if you want to be on 1.9 MHz, which is in the middle of the band, set your vfo to 4, (1.5 + .4 = 1.9 MHz). In actuality, when the vfo is set to 4, it is .4 or decimal 4.

Be careful to stay inside the ham bands.

Good Luck,
Kevin - N2FLP

If everything in the TS-530 were left the same except the 160 meter band switch front panel setting is labeled "1.8" instead of "1.5" AND the operator tuned his VFO to the first large tick mark above zero, thinking he/she is at the low end of 160 meters, what would the frequency the TS-530 be transmitting on?

"1.550Mhz"
which is not part of the 160 meter band. The same applies to the 30 meter band. The band switch indicator for 30 meters is "10" not "30". If the VFO is left at zero and the operator tuned up the transmitter, the TS-530's transmit frequency would be "10Mhz", same as 10Mhz WWV which is not part of the authorized 10.1Mhz to 10.150Mhz 30 meter amateur band. The band switch "10" is added to the VFO analog dial to indicate the frequency the TS-530 is tuned to. If the VFO is tuned to the first tick mark after "100" on the analog dial and the band switch is set to "10", the TS-530 would be tuned to and transmit on 10.110Mhz, 10Khz inside the authorized 30 meter amateur band.

Learning how to read/use the analog dial is easy. One complete rotation of the VFO knob results in an increase or decrease of 25Khz.

If you are saying you have no modulation with Processor off (switch pushed in) turn radio over and locate the GEN board. Locate the NOR (Normal) wire wrap post. It typically will have a green wire on it. Connect voltmeter to NOR and ground. Should see approx 7.0vdc. Now pull out Processor switch to ON and the 7.0 vdc should go to 0. The 7vdc is used to forward bias Diode D18 to complete the normal mic audio path. Never seen a bad D18 switching diode, but possible.

55551. Hybrid Net Update (September 25, 2016)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-09-25 22:45:23 UTC
From: Mark Gilger
Topic: 55551 Message: 55551

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by me, WB0IQK. There
were 12 stations checking in under good band
conditions. The net was terminated early due to a thunderstorm in my area.

We had the following number of radios checking in.

0 running TS-520(x)
2 running TS-530(x)
0 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running TS-515
0 running 599 twins
0 running TS-900

I was running my TS-830s + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
8 stations checking in fairly good band conditions.

We had the following number of radios checking in.

2 running TS-520(x)
1 running TS-530(x)
0 running TS-820(x)
4 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830s + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins

55552. TS-820s Plate tuning capacitor question

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-09-27 15:31:00 UTC
From: wayne.bowyer@...
Topic: 55552 Message: 55552

I've acquired an 820s that I am slowly working my way thru an alignment. I've noticed right away that while tuning the transmitter (into a load) that the plate control setting(when tuned to resonance) doesn't necessarily correspond with the markings on the front panel. For example when plate control tuned for 20 meter output the control ends up being upwards of the 10 meter spot on the dial markings. I then pulled the case cover and then the cover over the final cage. When the plate control is set to precisely the 9 o'clock position the actual capacitor rotor is up or unmeshed (not sure if that's the correct term) about 25° (on the right hand side of the capacitor). Another way to put it......when the plates are fully meshed the plate pointer is at approximately 4 mhz +/-. I don't see anything in the service manual about proper setting but I remember from my Heathkit HW-101 days there is an alignment of the capacitor pointer vs the actual rotor/stator.
Any input is appreciated!

Wayne,
This is not unusual, and the pointer indication is not intended to be EXACT and is mostly a "relative" indication. It is possible however, that over time and ownership that the set screws have loosened...and the shaft slipped for what ever reason. There is/are no directions in either the operators/owner or service manual regarding this. Maybe the prior owner may have adjusted the pointer to indicate what it should point for his/her particular antenna installation. If it is un-nerving for you, fully mesh the plate tuning cap, loosen the set screws on the shaft coupler, and rotate the knob/pointer so the pointer points to "3.5" or approx " 9 o'clock." Turning the newly repositioned pointer clockwise...when the plates are appox. 50% un-meshed...the pointer will be pointed approx at the middle of "14.," or about 1300(1 o'clock). 100% un-meshed the pointer will be at approx "28" or approx 1500 (3 o'clock) It does not matter which way the cap plates mesh/un-mesh...just the the pointer may be pointing down instead of up.
These indications are "relative." Tuning into a good 50 ohm dummy load, and then straight into a...say a dipole(no tuner), may cause the pointer to point at something other than what it did while you were transmitting into a dummy load

55554. No PWR OUT on 160M/Low PWR Out on 80M

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-09-27 20:37:13 UTC
From: k1hh@...
Topic: 55554 Message: 55554

Hello Group:
I have a new to me TS0520se. Here's my problem.
The unit shows good Drive levels on all bands 160-10M. It has good RF out on 40-10 meters. It has NO RF transmit out on 160M and has varying amounts of RF out on 80M. Its strange on 80. At the LOW end of the band, say 3.5 to 3.65 it has maybe 80 watts out, but 3.65 up to 4.0 the RF output drops to 30-40 watts.
I have done a coil pack alignment, excluding HET OSC. I have cleaned the bandswitch with Deoxit, HV appears good, radio receives well. I have read an excellent article online about possible final cage problems.
Any suggestions from the assembled membership of this forum is appreciated.
Thanks in advance,
Rodger K1HH

Fortunately it is easy to test the Tank Capacitor fixed padder caps if you have a digital LCR bridge. There are three caps involved... 390pf, 100pf, and 12pf.

1. Remove covers and turn rig over.
2. Remove 3 screws that secure the S5 switch cover plate (near Ant TR Relay)
3. Will see the three caps near the Ant TR relay.
4. Place bandswitch to 40 meters or higher.
5. Will see two bare leads leaving the padders and terminated on the S5 deck. One lead will have the parallel combo of 390pf and 12pf caps and the other lead will have the 100pf cap.
6. Measure each lead individually to chassis ground. Should read approx 400pf on one lead and 100pf on the other.
7. If grossly off then replace.
8. If close to spec then try cleaning the contacts of the S5 switch and repeat reloading on 80 and 160.

The padders should be replaced with Class 1 temp coefficient caps. May be difficult to locate. If cant find them then use Class 2 at no less than 3kv rating. There is approx 1600 p-p rf volts across these caps at 100 watts output.

Hello,
I have a TS 820 with the display unit. When I have a station tuned in good,the display is off 100hz to 1kc depending on the band I am on. i checked it also with the 25khz marker.

It reads high on the following bands in receive.

80m 100 hz
40m 2-300hz
20m 500hz
15m 800hz

10m 1kc

Thanks

You can try adjusting the Counter Mixer board reference clock trimmer cap. It is accessible thru small hole in top of the metal shield can.

If you have a strong copy on a favorite net (might try Maritime Mobile at 14.300) you can tune the VFO for a natural voice and then adjust the trimmer cap until the digital display reads the net frequency. In this case 14.300.0.

Can also adjust if you have a decent frequency counter, but today with all the modern newer DSP rigs in service you can use them as your frequency standard. Just as good and maybe easier than zero beating WWV.

As to your 25khz Marker oscillator (crystal calibrator). It is not uncommon for it to be significantly off. Can adjust it with good frequency counter or by zero beating against WWV. Very common not to be able to zero beat regardless of where you set the trimmer cap. This is due to crystal aging. If you run into this there are some tricks you can try to pull the crystal frequency like tack soldering a small value fixed padder cap across the crystal pins.

Try adjusting Counter Mixer unit TC-1 trimmer first. Disregard the Service Manual directions to use a calibration cable as note in Step 3.1. Just try adjusting against a net that you have good copy on in your area where you can adjust the VFO for natural voice.

Hello to the Group,

I have a Wavetek SG-1170/U that is in need of service. Looking through the archives, I have seen the name Dennis McGrew, K8IFF as a Guru on these units. I do see him on QRZ but was wondering if anyone here has his contact info or knows if he still services these units. I appreciate any help on this.

Thanks Terry.

I don't have bridge since I closed my shop. Guess I need to get a more modern one anyway. I see the AADE bridge is no longer offered so I'll look for an "import." Any suggestions?

I found the caps this morning. Looking at the connections, I think someones been there before me. I did order and have just received four 100 pf, 6000V caps. They are unmarked but advertised as Ceramite brand. I sometimes use westfloridacomponents.com here in Florida as a vendor and they had a couple of caps that I though might work. I did use some more deoxit (on q tip) on the switch. I'll try to put the 100 puff in tonight or in the morning when the garage is cooler and my hands are steadier. Thanks for the reply to my post. It looks like I double posted. I think because I'm a newbie on the list my original post was held up for a few days.

I like your website and its great that you share your knowledge so willingly.

55562. Logitech HD Webcam C920 Launcher_Main.exe error

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-09-28 22:03:49 UTC
From: Mike W5RKL
Topic: 55562 Message: 55562

All members,

I use a Logitech HD Webcam C920 software and camera to produce the videos on my website. I don't know how many, if any, group members use this software and camera but if any of you do and you are experiencing the "Launcher_Main.exe" error after the "Anniversary" update to Window 10 and can't figure out how to use the HD Webcam VIDEO recording option, read the following, it's what I found that works to get around the error.

I read a lot of the discussions on the web concerning this error and the suggested temporary fixes including fixes found on Logitech's website. I found none of the recommended fixes worked nor did the 2 links Logitech sent me as a fix for the problem. I've even seen suggestions to make changes to the computer's "REGISTRY" which I do NOT recommend doing!!!

Here is what I found that provides a temporary fix/work around to allow the user to use the Quick Capture "VIDEO" option to make VIDEOS or possibly streaming video on the web through Social Media. The temporary fix is to change the default setting to Logitech HD Webcam software's Quick Capture camera window from "PHOTO" to "VIDEO". This is how I made the software work to record video:

1. Connect the camera to the computer's USB port. You can check Control Panels' "Device Manager" to ensure Windows sees the camera which it should.

2. Launch the HD Webcam C920 software

3. Click on "Quick Capture"

4. When the camera window shows up, "QUICKLY", and I mean "QUICKLY" select "VIDEO" option on the lower left corner of the camera window before the "Launcher_Main.exe" error window shows up. The error will occur within a second or 2 after you click "Quick Capture" so you don't have a lot of time before selecting "VIDEO" as the Quick Capture camera windows setting. If you are successful, continue with the following, otherwise shut the HD Webcam software down, wait a minute, then perform steps 3 and 4 again.

Next, click on Preferences in the upper right corner of the software window. When the Preferences window opens up, click on the "Quick Capture" tab and slide the microphone fully to the right (100%) then click "Save". You can make changes to the "Gallery" tab's video, photo, and motion detection folders before clicking "Save".

Next, launch Windows Control Panel and click on the "SOUND" link. A new separate window will open with tabs along the top. Click on the "RECORDING" tab. The window will switch and show the microphone labeled

"HD Webcam C920 Default Device" as the microphone.

Double click on the Microphone and a separate window will open with tabs along the top. Click on "LEVELS" and slide the microphone level to 100%.

Making the microphone input changes to 100% is because this problem has affected video recorded audio resulting in lower than normal audio levels in recorded video audio. Increasing microphone input levels to 100% provides a better video recording audio. Once the problem is solved by Microsoft and Logitech, the microphone levels will need to be changed to suit your needs.

Next, click "OK" to close each window.

Next close Control Panel, you're done.

The "Webcam Gallery" and "Quick Capture" VIDEO features work without the error but only if you follow the above steps. The Quick Capture "PHOTO" feature does NOT work and if that option in Quick Capture is selected, the Logitech Webcam software WILL crash with the "Launcher_Main.exe" error. This means you can't take snap shot Photos with the Logitech C920 camera using the Logitech Webcam software and C920 camera until Microsoft and Logitech provides a permanent fix for this problem.

After completing the above steps you can disconnect the camera at any time, shut the software down at any time, shut your computer down, reboot your computer at any time, put your computer to sleep or hibernate, and the software will still launch and work in Quick Capture camera window "VIDEO" without the error providing you do NOT select Quick Capture camera window option "PHOTO". If you accidental select PHOTO you will have to go through the above procedure of selecting the camera window's "VIDEO" option again but you will not have to mess with the microphone settings. The software crashing does not affect the Preferences and Camera control settings.

Not uncommon on the 820 and 520 series rigs that cross my bench to find that the Marker oscillators can no longer be adjusted as the xtal has aged. The trimmer cap no longer has enough range. Usually can pad it to pull the frequency enough so that the trimmer can bring it in.

Adjusting the Marker osc trimmer has nothing to do with Digital Display being off from actual receive or transmit frequency. The Digital display has its own reference oscillator that aligns the Display to actual operating frequency.

Marker (xtal calibrators) were important in the old analog dial days (especially if you wanted to avoid a pink slip), but I doubt many folks who have KW hybrids with Digital Displays use the Marker function very often.

For those who have no test gear the Marker is tool that allows them to perform coil pack alignment.

You shouldnt have to turn TC-1 trimmer very far. May indicate aged xtal.

There are two different DG-1 Counter Mixer boards. One version has a better reference oscillator circuit in addition to a carrier null pot for Mixer IC-1. Rev 13 board uses a 10mhz clock and the earlier Rev 3 board uses a 1mhz clock. The later circuit (Colpitts Osc) is used in the 530/830 rigs as well.

You can measure and monitor the oscillator frequency at Molex Conn CL-1 with Freq counter. Can see if able to set output spot on with the trimmer. If you cant, you may need to pad the crystal (start with 10pf) or purchase a new one. I have never had to buy a new one but suspect that International Crystal could supply one. Might have to send schematic to them so they can calculate the circuit load capacitance in shunt with the crystal pins.

See the Service Manual Step 2-1 Item 3. FSK SPC should also list CW. With mode switch in CW connect Freq counter to TP-5 on IF board, flip to Send, and adjust TC-1 (Car-2) for 8830.700.

You can also adjust USB and LSB trimmers before above step, but dont spend a lot of time trying too set them to precisely at the noted frequencies. This is just starting point for bringing the carrier oscillators to the IF filter. 4 or 5 ways to adjust TC-2 USB and TC-1 LSB trimmers. The best way is using audio injection into mic line to set the 6dB roll off on the wattmeter. Requires accurate frequency and output and stable audio gen or arbitrary waveform gen.

Methods include:
1. Set using frequency counter
2. Use the marker and S-meter zero beat method
3. Use the moni and set for your natural voice
4. Use audio spectrum analyzer software and diode noise generator
5. Use audio generator mic injection and wattmeter method

Adjusting the Carrier Set Point has element of personal preference to it. Some like more bass sound and others prefer more treble presence for more communications style audio especially if running barefoot.

55570. TS-820s displayed frequency question (s)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-09-29 23:50:19 UTC
From: wayne.bowyer@...
Topic: 55570 Message: 55570

I have a new to me 820s. Picked it up for a song at a local hamfest a couple months ago. I don't think the previous owner really understood the nuances of these old hybrids. I've a a 520se so I have a little bit of experience with these. The 520 and 820 line of rigs were my dream radios when I was first licensed in 1978. But in '78 I was a 23 yr old new father and there wasn't enough money for the Kenwood so I built a HW-101 and that was a better fit for the family budget and gave me valuable experience at the same time.
OK...on to the 820. I know these have a history of display issues. This one is pretty during operation but it does have a quirk when powered up. For example......if powered up on 40 meters and the VFO/dial is set on 7.100 mhz, it will come up displaying 7676.2 or thereabouts. You can spin the VFO knob and makes basically no difference in displayed frequency. Now if I simply change the band switch from 40 to 20 and then back to 40 it will display the proper frequency and operate normally. It only does this odd frequency display thing when powered up. And it does basically the same thing on each band. Comes up +500-600 kc's on each band and then goes normal when switching the band switch back and forth.
What's going on here?

Topic: 54481 Message: 55573

Welcome to the Yahoo Kenwood TS-520_820_530_830 Amateur Radio Group. This group is comprised of members who's interest is in maintaining and operating the Kenwood TS-520, TS-820, TS-530, TS-830, TS-510, TS-511, T-599/R599 and R820 Hybrid transceivers, transmitter and receivers. In addition, the group supports discussions covering the associated Kenwood accessories such as the VFO-520, VFO-820, VFO-230, and VFO-240 remote VFOs, the Kenwood antenna tuners, and the various Kenwood desk and hand microphones.

This is a restricted group requiring membership approval prior to receiving and posting messages to the group. To join the group simply complete the Yahoo Kenwood TS-520_820_530_830 Group's application process by clicking on the “+ Join Group” icon on the group's homepage. Select the desired method of receiving messages by clicking the appropriate radio button, then provide a brief description about yourself to include: your first name, your Amateur Radio call sign, your interest in the Kenwood hybrid radio, and the model of Kenwood hybrid you own, operate, or in the process of purchasing in the text box provided. If you are not a licensed Amateur Radio operator, no problem, simply complete the application process and provide the same information less the Amateur Radio call sign. Once you have completed the text, click the Join Group icon. Your application will be reviewed and approved by a group co-owner or Moderator. If you leave the application text box blank, your application for membership will be rejected. Simply reapply and provide the information requested and resubmit your application for membership.

New members are placed on a "Moderate" status. This means that any message a new member posts to the group must be approved by a group co-owner or Moderator before it appears on the group server for all members to see. The length of time a new member remains in a "Moderate message status" is determined by the members ability to adhere to, and follow the group's policies. The faster the new member(s) can prove they are adhering to, and following the group's policies, the quicker the new member's status will be changed to “Allowed”.

The “Allowed” status means the member can submit/post their messages without group co-owner or Moderator's approval. A member who's message status is set to “Allowed” may have their message status changed to "Moderate" if it is deemed necessary by a group co-owner or Moderator for one of the following reasons:

1. Failure to follow the group's policies after being informed by a group co-owner or Moderator
2. Knowingly violate any of the group's policies
3. Any improper behavior by the member that is deemed inappropriate by a group co-owner or Moderator

The group is moderated by both group co-owners and group Moderators. While we would like to have a group co-owner and/or Moderator present 24/7, that is not possible, as group co-owners and Moderators have a life too. Therefore, there will be times when a group co-owner and/or a moderator will not be present. This will affect the time a moderated member's messages may take to get approved/rejected. This occurs most often during major holidays Also, the group's server is not maintained by the group co-owner(s) or Moderators.

Therefore, when Yahoo has problems affecting Yahoo Groups, ALL members will simply have to wait for Yahoo to fix the problem. Group co-owners and Moderators also do not have any control over how the group's server handles attachments to messages or how message search results are provided.

Page 1

As stated above, this group has a set of policies that all members must agree to and abide by. If any member, new or old, that feels they cannot accept the group's policies, that member is free to terminate their membership at any time without notifying the group co-owners and/or Moderators.

Group's Policies:

1. Profanity of any type, regardless of the word and/or phrase(s) used in a message, is not allowed. This includes the use of abbreviation to improper words, use of symbols to substitute for letters, etc. In short, the use of profanity is NOT ALLOWED, PERIOD!!! The quickest way to get banned from this group is to use profanity!!!

2. Disrespect/Flaming any member regardless of the reason, is not allowed.

3. Taking over a thread by a member that changes the threads original subject and content, is not allowed.

4. Messages that contain as part of the message text, discussions of a member's private life are not allowed. Responses to messages are to pertain to the original message subject.

5. Long discussions that are products of an original messages are not allowed. If there are 2 or 3 members who wish to discuss a subject in more detail and at great lengths should take their discussions off the group and continue their discussions using private email addresses.

6. MESSAGES THAT DO NOT CONTAIN ACCEPTABLE MESSAGE SIGNATURES, WILL BE SUMMARILY REJECTED! It takes less than 5 seconds to ensure your message contains an acceptable message signature. There is no excuse for not adding a message signature to your messages. Political or religious signatures/statements are not permitted.

The following are examples of the ONLY acceptable message signatures:

Licensed Amateur Radio members:

Example:
“73s
John WA1ABC”

Non-licensed members

Example:

73s
Mary

If a member does not wish to include their Amateur Radio call sign in their signature, then simply use their first/given/Christian name ONLY, same as non-licensed members.

Each message signature must be positioned at the bottom of the message text and separated by at least one line.

For example:

Hi John,

Yes capacitor C25 is the right cap you should be checking. For details, review the schematic.

73s
Bill

Screen names such as JLH524 or MWPO125 are not acceptable message signatures. Screen names are acceptable ONLY when used as part of the member's email address.

The member's email address is not an acceptable message signature, regardless whether the member's name appears in the email address or not.

A member's “initials” are not acceptable as a messages signature.

A member may add up to 2 additional lines to their message signature. The additional 2 lines may contain a link to the member's website and a link to the member's Amateur Radio club etc. The addition of 3 or more lines to the message signature, listing the many different clubs the member belongs to, the positions they hold within the respective club(s), their professional position within the company the member works for, and other information is considered excessive and not allowed. The following is an example of an acceptable message signature containing two additional line:

Mike-w5rkl
www.w5rkl.com
Yahoo Kenwood TS-520_820_530_830 Moderator (Mike-w5rkl is no longer a Moderator, but used as an example--tnx)

In the past there have been members who state our group policies are too strict. We maintain strict group policies for 2 simple reasons:

1. To maintain good order and discipline in the group.
2. Provide a friendly group where all members are treated equally and an environment free of improper behavior

73
Yahoo Kenwood TS-520_820_530_830 Hybrid Group Co-owners and Moderators.

55574. File - Rules, For Sale or Want to buy Posts

Yahoo group: TS-520_820_530_830 (2015 — 2016)

Rules pertaining to Occasional For Sale and Want to Buy Posts.

Members of the TS-520_820_530_830 Yahoo Group who have been members for at least 30 days may place " for sale" posts no more frequently than two in any 30 day period." Want to buy" posts are permitted immediately upon membership and are limited to 2 in any 30 day period.

For sale posts are limited to the sale of TS-510, 515, 520, 820, 530, 830, and the 599 series twins, as well as Kenwood accessories intended for use with these radios.
Also, group members may post "service equipment" for sale. This may include, but are not limited to: vtvms, various signal generators, and other testing/service equipment. Posts must include: the make and model of the item for sale, as well as an accurate description of its condition, and the asking price.

When the item is sold, please make a short post to that effect.

Replies and discussions regarding these posts must be taken off of this group either by direct e-mail to the seller or as directed by the seller.

Buyers and sellers are on their own. The TS-520_820_530_830 Yahoo Group, its owners, co-owners, moderators, or members other than the seller, hold no responsibility for the accuracy of the posts or the credibility of the seller or buyer.

We do not expect that members of this group will misrepresent, or in any way cheat other members. At the co-owners(s)/moderators discretion, we may choose to ban any member from making further for sale posts, or ban the member from this group entirely if we believe their posts or transactions are not of the utmost integrity.

We ask that those who buy and sell equipment as a main business not post here. We will allow posts from members who occasionally restore and sell equipment/accessories as stated above.

We expect our members to use discretion. If excessive traffic develops as a direct result of these postings, they may have to be discontinued.

Walter Breining, N9WB
Joseph T Stiles, WB7UQU

Wayne,

Have you tried cleaning the band switch wafers? It appears as though the switches may be dirty.

The DG-1 digital display module has an "edge connector" found below the chassis. You might remove it and clean the DG-1 display modules edge and the connector itself. You can see how to access that connector in the TS-820 service manual.

The picture below is the Kenwood DG-1 digital display module found inside the TS-820S. The picture shows the DG-1 digital display module which contains 2 PC boards, one is the Counter Mixer X54-1150-00 and the other is the Counter X54-1160-00. The digital display tube X54-1170-00 is shown connected to the DG-1 through the plug in multi-wire connector. What is not shown in the photo is the small square 5V-AVR X43-1220-00 board mounted above the chassis atop a hex metal post directly behind the DG-1 module. The TS-820S can operate without the DG-1 digital display.
Image result for TS-820S

55576. TS-820w VFO removal

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-10-02 15:27:13 UTC
From: Scott Hollis
Topic: 55576 Message: 55576

A quick hello to everyone in the group. I recently joined as I've obtained a very good condition TS-820s. Some stains/scratches on the faceplate/knobs and display lens.Intererior however is very nice. I believe this unit has been sitting for awhile. Not too much dust but scratchy pots and the purpose of my post.....my nemisis.. the VFO unit.

I noticed when turning the VFO, I would get a signal dropout and a slightly rough feel when the dial reached a certain area of movement that is repeatable at eachpass. Dreading that the capacitor plates may be rubbing against each other, I decided to remove the VFO unit and check it out.

My first problem was removing the 4 mounting screws. The two top and one bottom came out fine. But the second bottom screw, after about 1 1/2 to 2 turns juststopped and wouldn't budge...period. No amount of lubricant or coaxing with a needle nose vice-grip(after stripping the head of course) would get it to turn. Severalnights of different tactics resulted in disappointment. Last ditch effort was to try a screw extractor which after several attempts, ended up twisting the head off.Not quite what I wanted but gets me where I want to go.
With that out of the way, I removed the two top screws and tried to lift the unit out. Still no go. The rear does lift but there is still something towardsthe front bottom part of the VFO that is keeping it from being removed.
Can anyone offer advice as how best to get this out and what possible cause could be interfering? I will point out the that the remainder of the bottom screw is stillattached to the bottom plate of the VFO. I'm assuming this was only holding the VFO plate to the plate attached to the chassis...if so, it should just lift out withthe rest of the unit.
BTW: I used the excellent PDF showing the disassembly here:
http://nr6c.com/VFO%20REPAIR.pdf
Thanks for any help you can offer.
Regards......Scott

55577. Re: TS-520S - Removing mods & SSB Output Issue

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-09-30 23:42:53 UTC
From: christopherlarwood@...
Topic: 51751 Message: 55577

SSB output is an intermittent problem.
CW seems consistent.
I may be able to use the radio for several transmissions without any signs of a problem.
This is after proper warmup and tune.
With no change to operating frequency or any other setting SSB output can drop to next to nothing. Switching to CW and it's 100 w solid.

Switch back to SSB and next to nothing. Mic gain sits about 11 oclock, processor off.

It's not the PA - is working fine in CW /Tune modes.
My settings and tune up process are correct - the SSB output is good when operating.

But can disappear without warning. The radio can have been in operation for 10 minutes or an hour when it occurs so don't think a heat matter. I put 5 or 6 long CQ calls out on 40/80 last night working normally. Then nothing.

Have tried different mics - same experience - fine then nothing.

Intermittent faults are hardest to pin down - any suggestions what I should be measuring or looking at?

55578. TS-820s digital display a bit erratic

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-10-02 02:20:33 UTC
From: Wayne Bowyer
Topic: 55578 Message: 55578

I recently bought an 820s that seems to be in pretty good shape. I've only found a couple issues so far. I know these have a history of display issues. This one seems pretty reliable, one quirk is often/most times when powered up regardless of band the display will read anywhere from 200-500khz high. Do a simple band switch back and forth and it will read drop back and read properly. I've done a simple spray cleaning of the band switch assembly with CRC QD electronic cleaner but it made no difference. Other issue and I've yet to start looking into it is no switching to transmit(receiver stays in rx mode)with a microphone plugged and keyed. I'm using the same D104 mic I use with my 520se. It will load to about 100W(Bird 43 into a load) in CW on most bands (a tad lower on 10) so at least part of the transmitter is working. CW signal sounds clean in my TS520se sitting near on the bench. Again I've just started looking into this rig, I'm not the sharpest knife in the drawer but I've got some simple test equipment, little bit of experience and a lot of time. Any nudge in the right direction will be appreciated!

From: Lou Blasco
Topic: 55579 Message: 55580

Hi Will,

I think you have to open it up. Get the service manual if you don't already have it as well as the large format circuits from K4EAA. In my view these circuits are easiest to read. Look in the top right hand corner of the circuit where you will find the main antenna socket. Trace the RX path down through the XVTER switch (S19-1) then through to the RF ATT switch (S6-1) You can see it is a simple attenuator. Follow the line out of the attenuator and you'll see it finally ends up at the RF Unit.

Regards

Lou

55581. Hybrid Net Update (October 2, 2016)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-10-02 23:30:33 UTC
From: Mark Gilger
Topic: 55581 Message: 55581

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by Jimmy, WB2KNR. There
were 13 stations checking in under good band conditions.

We had the following number of radios checking in.

5 running TS-520(x)
3 running TS-530(x)
1 running TS-820(x)
1 running TS-830S
0 running TS-510
0 running TS-511
0 running TS-515
0 running 599 twins
0 running TS-900

Jimmy was running a TS-520 + Heathkit SB200.

The Sunday net was run by me, WB0IQK. There were
11 stations checking in fairly good band conditions.

We had the following number of radios checking in.

3 running TS-520(x)
0 running TS-530(x)
1 running TS-820(x)
4 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830s + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

Scott,
You do not need to remove the vfo to clean the rub plate. Look on the right side of the vfo, looking from the front. You will see a plate that has a two screws in it. Remove the rear screw and rotate the plate upwards. You will see the rear of the capacitor and the rub plate that needs to have several drops of DeOxit D5 put on it. Once you do that, rotate the vfo knob from one end to the other as many times as needed to eliminate the problem. Sometimes it only takes several times back and forth, other times it takes a lot. I just did a TS-520S and it took probably 20-30 times to clear up the problem.

If you are intent on removing the vfo, here is the full procedure.

Connect your ohm meter between the center pin on the SO-239 antenna connector and test point TP-1 on the RF board. Should read under 1 ohm, but will likely be higher due to dirty NC contact on the MX-2P Ant TR relay.

While monitoring the resistance exercise the RF attenuator mini-push button switch. Should see very close to 470 ohms (470 plus whatever you read with the attenuator off).
Very common to have bad/dirty contacts on all of the mini PBs. Very hard to get any meaningful amount of contact cleaner into the switch body as nearly sealed units. As you monitor the resistance exercise the grey PB including rocking and pulling and pushing (gently) to see if you can restore consistent 470 ohms.

If mechanical actuation doesnt work, can clean the switch electrically if careful. Use 5 to 6vdc current limited to 1 amp and can clean the Ant TR relay, the Xverter mini din switch, and the RF attenuator switch.

Thanks for that Mark. I was able to get the VFO free from the chassis. There was a piece of foam/rubber along the bottom that the VFOwas sticking to. It was also hanging up on a pot casing. Opening that 'hatch' showed no issues with bent blades. I did spray all blades andwhat I believe is the wiper (located towards the rear as bowed piece of metal surrounding the shaft?). Doesn't look like much of a connection but that got the Deoxit also. I then put some lithium grease on the ball bearings located on the front of the shaft and on allthe dial gears. I hope to get things together and finished cleaning by mid week for a test. The grease seemed to get rid of the roughspot but there still is a bit of resistance when turning the larger outer brass ring. I always thought the VFO was butter smooth??
Thanks again....Scott

Is there a reduction of the S meter reading by a few S-units with a signal when you turn on the ATT? Any reduction in the background noise without a signal tuned in ? With a good AGC circuit there may be no reduction of the signal in the speaker when there is QSB ! Try disabling the AGC and try the ATT on & off test again.

My TS830s RF Attenuator circuit appears not to be functioning. Although when I depress the front planel button and the red led indicates its in circuit, there is no reduction in af through the speaker at all. Before I open up and start to troubleshoot, wondered if anyone could suggest a good starting point and, what methodology I should follow and what to check for. Many thanks. Scott,

There is no need to spray contact cleaner on the variable capacitor fixed and variable "plates" (blades as you called them). It's not recommended to spray large amounts of contact cleaner. You should use only enough cleaner to do the job. I clean band switch wafers and VFO variable cap flex connections using a cotton swab wet with cleaner. I also use a old child's tooth brush wet with cleaner to "gently" scrub the wafer switch. I then follow with generous amounts of canned air to remove any/all cleaner residue where ever it is found. I have never experienced any damage or failures to wafer switches whether the wafer switch is Phenolic or Ceramic by using this method of cleaning.

I removed the cover of a TS-820 VFO to show the location of the capacitor's flex connection.

Front view of the capacitor shaft showing only bearings, no flex connection. The ball bearings do provide connection between the shaft and frame. I apply DeoXit L260Ap grease to the ball bearing when cleaning the VFO after cleaning the bearings.

Rear view of the VFO capacitor shaft's flex connection. This is the area that I clean with DeoXit D5 applied with a cotton swab and pressed gently down on the shaft next to the flex connection. This allows the cleaner to soak into the flex connection. Rotating the VFO throughout its range 3 to 4 times allows the cleaner to remove the dust and corrosion build up. This cleaning process quite often is required to be repeated 2 to 3 times depending on how dirty the flex connection is. I then use generous amounts of canned air, compressed air can also be used, to remove any/all residual cleaner residue. I inspect the surrounding area, coil, and other components plus the PC board for evidence of cleaner. If found I remove it with canned air.

When the VFO is out of the radio, you can test the VFO using a scope and a +9VDC power source. As seen in the picture below, the VFO is powered by separate power source, a Heathkit IP2718. The right DVM displays the stable +9VDC while the left DVM display the 13.4ma of current flowing in the VFO. The VFO enclosure is not required to be removed to test the VFO, I simply didn't put it back on when the picture was taken.

I provided these pictures to show the internals of the VFO and how to test the VFO when it's out of the radio. The VFO shown has a bent front plate on the gear assembly which allows the backlash idler gear to fall out of its mount. Other than that the VFO works and produces a clean and stable RF sine wave throughout it's 4.9Mhz to 5.5Mhz tuning range.

I have a video on my website, see the link below, where I show how I clean that flex connection on VFO/LMO variable capacitor shafts. While the video does not include a Kenwood hybrid VFO, the flex connection shown in the above picture and the capacitors shown in the video show similar flex connections. The HW-101 LMO has flex connections at both ends of the capacitor shaft. I state in the video that the Kenwood hybrid VFOs have the flex connection at both ends of the shaft. That's not true with the TS-520 and TS-820 VFOs as they have only one flex connection. I can't speak to the TS-530 or TS-830 VFOs, I don't have either VFO to verify whether they have flex connections at both ends of the capacitor shaft.

Hi Mike,
Thanks for the reply. I have cleaned what I could easily get to following the band switch shaft underneath the rig. I used CRC QD electronic cleaner. Didn't really affect much. But I have not fully cleaned the edge connectors on the display unit. I won't be able to get to that till maybe tomorrow evening. I'm kinda/sorta retired but work p/t couple days a week at a local hardware store. Work tomorrow so it will be Wednesday before I can take another serious look at it. I have some SSB tx issues I will also need to figure out so once I am satisfied with the display problems (not a real serious issue though). Once I make some more measurements (so I can ask intelligent questions) I will be posting/asking more questions! Thanks so very much for your help so far.

Ok,
I adjusted TC1 on CAR 2 to 88307.00 with a freq counter on TP 5. My cw TX offset is now +600hz.
If I adjust TC1 to 88305.00 the offset is at +800hz. Is that ok? I have a 500hz Cw filter in the radio.

The first and easiest thing to try is cleaning the connectors. Because of its age, the display connectors get oxidized and can cause intermittent conditions. Carefully clean all the associated connectors (and pins). This is most likely your problem (assuming when the display reads off, the radio is actually on the correct frequency). Some of the signals are very low and good connections are required.

DeOxit used SPARINGLY (I use a wetted Q-tip) will help clean the contacts.

If this doesn't help, there are other things to check.

G'day,
Your tube looks normal, but looks aren't everything. If your getting good power output on some hands and not others, could be the wafer switched may be dirty, the miles connectors may have driven joint or have z build up of corrosion on pins, all very common for this radio.
Must pay Attention to ensure no hv when dealing with these radios. also just be careful removing and cleaning molex connectors etc.

If it is intermittent it is unlikely the tubes are at fault. Likely a dirty switch wafer. Just last night I replaced the original 6146's {S2001} tubes, 39 years old in my TS-520S. They were fine on 3.5 and 7 mhz with 110 watts out, dropping to 80 on 14 mhz, then 40 and 30 on 21 and 28mhz respectively. New finals brought it back to spec.

Subject: Re: [TS-520_820_530_830] TS-830s low power output

G'day,
Your tube looks normal, but looks aren't everything. If your getting good power output on some hands and not others, could be the wafer switched may be dirty, the miles connectors may have driven joint or have z build up of corrosion on pins, all very common for this radio.
Must pay Attention to ensure no hv when dealing with these radios. also just be careful removing and cleaning molex connectors etc.

Hi Everyone,

This is Shrini and this is my first time posting here. My TS-830s has low power output on 20m and higher around 40 watts vs 90+ watts on 40m. Sometimes it will show 90+ watts on 20m but only intermittently.

I check the cathode and screen resistors and they are within spec but both final tubes (GE 6146B) have a black discoloration inside the envelope behind the little ring also inside (not sure what that is for). I took a picture that can be seen here Imagebin - Somewhere to Store Random Things<https://imagebin.ca/v/2xKvNZqk4TkO> Does this mean my tubes need to be replaced or is there something else I should be checking. I would appreciate your help to fix this. Thank you.

Do an alignment and see what it does.It could be a dirty band switch also.

I believe the discoloration inside the envelope is from the process that removes the last bits of gas from the tube in the factory. Not an indication of any problem. Tubes still could be weak but if they work on 40M it is another problem. My radio is Ham Radio...CW is Real Radio 73, John...K8JD

55602. TS-820 mode switch and re-cap

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-10-05 21:15:26 UTC
From: Phil Erickson
Topic: 55602 Message: 55602

Hi all,

I've just acquired a TS-820 and I'm beginning the restoration process. I have the high-res schematic. Two questions come up:

1) During initial checkout, I noticed the BAND switch does not 'snap' between its settings (TUN / CW / USB / LSB / FSK) and feels 'mushy'. Can someone out there with a good TS-20 tell me whether that switch is supposed to have positive click detents for each setting?

2) On a rig of this age with unknown history, is the conventional wisdom to do a complete or partial re-cap prior to checking and aligning, or can I get away with a 'power up on a variac and check performance'? If a recap is recommended, can I save time by focusing on particular caps?

Phil,
Your subject line mentions the "mode switch," but the body mentions "Band switch. The mode switch should NOT be mushy...and should feel crisp and with positive detents. The band switch should also feel crisp and have positive dentents. The band switch is not a straight connection like the 530/830 series. It two white nylon cogs connected by a chain. You can see the band switch shaft coupler through a small square opening on the underside of the rig between the calibrator board the the CAR ASSY(carrier assembly) Most of the 820's have a rather robust coupler made of a brass insert inside of a phenolic body..and rarely cause problems...some very late production rigs may have either a black or white nylon coupler...which will often crack at the set screws..a problem that also plagues the 530/830 series. I would inspect this to see if all is well.
The topic of automatically totally re-capping has been brought up numerous times here in the group...the consensus is: it's your rig..you can do what you want...also the consensus is that the HV filter caps C-21 & C-22 that are right behind the VFO..should be replaced..as a catastrophic of one will really ruin you day..and your rig. Several kits are available from either hybridrestore " dot" com or k4eaa "dot" com. Also, C-23 & C-24 at the left rear, are the screen voltage filter caps...usually don't cause a problem..but may be worth replacing too.....parts from the above mentioned

Phil,
Some amplifying info: it is not necessary to totally re-cap your 820, except for the ones I mentioned prior. Doing a total re-cap may induce faults that your rig did not have before, as some of the screen printing for the electrolytics has been found to be wrong!...but, it's your rig...you can do what you want. Take care of the already mentioned caps...then fire it off...whether you choose to use a variac or the light bulb method is your choice. It's also a good idea to get some DeOxit D5 or similar, and some canned air...and clean the controls and bandswitch wafer contacts.....just my dimes worth

Hi Joe,

Thanks for the information. I mistyped in the body and it is indeed the MODE switch (CW/USB/etc.) that is not crisp. Fortunately, the BAND switch appears just fine. I'll pop the hood and check into the MODE problem. Regarding the caps, your answer is exactly what I was looking for and I'll stick to the 4 suggested ones as being good insurance so to speak.

Looks like I found the right group!

55609. Re: [TS-520_820_530_830] TS-830-S blank readout

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-10-07 11:34:46 UTC
From: W5RKL
Topic: 55607 Message: 55609

The "FIX" option requires a crystal within the frequency range between 5.5Mhz and 6.1Mhz. The crystal is not supplied by Kenwood, it is a "User" supplied crystal with a frequency determined by the formula shown on page 21 in paragraph 4.5 in the TS-830 user manual.

If you read paragraph

"4.5 FIXED CHANNEL OPERATION"
on page 21 in the TS-830 User manual, you will see how to calculate the required crystal for "FIX option operation.
For example, lets assume you want to operate fixed channel (crystal control TX/RX) on 7.2Mhz on 40 meters. You would require a crystal frequency of 5.7Mhz plugged into the fixed channel crystal socket inside the TS-830.
The required crystal frequency is calculated using the following formula:
5.5 - x + operating frequency
where
"x" is the band switch setting such as 3.5, 7.0, 10.0, 14.0 etc.
"Operating Frequency" is, in this example, "7.2Mhz".
therefore we use simple math to calculate the 5.7Mhz crystal frequency as follows:

5.5 - 7.0 + 7.2 = 5.7Mhz
The "5.5" is the internal or external VFO output frequency at the bottom of ALL BANDS. Calculations always starts at the bottom of the band's VFO output frequency.

The crystal is housed in an HC-25/U holder and is a "Fundamental" frequency crystal. Crystal tolerance is .002% and is a plug in crystal.

The crystal can be purchased from on line sources such as International Crystals in Oklahoma City, OK. Be prepared to pay a high price for the crystal. Most crystal manufacturers, such as Jans Crystals and International Crystals, charges a high price, approximately $50+, for crystals in the 5Mhz and below range. Contact either crystal source for further details.
http://www.jancrystals.com/
http://www.icmfg.com/

The FIX crystal option simply "replaces" the TS830's VFO, whether internal or external VFO. Selecting FIX option without a crystal in the proper frequency range in the FIX socket, the PLL Unit will change from a LOCK state to an UNLOCK state resulting in loss of digital display and both RX and TX will no longer work.

My
newly acquired TS-830 is working fantastic in all modes and
switch positions. It has been used daily on CW and is
everything I expected.I
have one question: When i push the "FIX" button
in, which has no crystal installed, the readout goes blank.
And when I release the button, allcomes
back normal. Is this normal? The manual does not mention
this possibility.
Thanks,
Rich K8UV

Wow..... sounds like a lot of fun for Errol........
Errol. if you can install HDSDR sw on your pc I have the complete set up.You will also have to install "Omnirig" to control the radio (CAT).
YES all the settings and offsets you need to get that Panadapter running .I do NOT know anything about the "Sharp" sw...Just a thought if you want to take the time and bother to get HDSDR installed.

The Kenwood TS-830 Survival Guide edited by DL9AI contains information about a mod to the VFO-230 (9.4 - page 28) which reduces the tuning rate to as low as 6 1/4 kHz per tuning knob rotation.

Has anyone done this mod and, if so, how has it worked out? The writer of the comment is not identified...

Thanks,
Chris

G'day,

I have seen and repaired a number of these so called modifications. Haven't seen one that works yet, but then again don't really know what they did apart from cutting diode matrix and adding jumper wires, sort of butchered the boards to some degree. But that's only my humble opinion.

If a remember correctly, Kenwood issued a VFO-230 service bulletin outlining this modification years ago. I did it to my VFO-230 and it did what it was suppose to do (lower the tuning rate). Personally, I didn't find much use for it. I assume because of the lower tuning rate, I did see more flickering in the units digit. I still find it annoying that I have to diddle with the VFO-230's AC cord every time I apply AC to the station in order for it to work. I kill all AC to the station when I'm done operating. VFO-230 always has to be plugged into live AC 24/7 to make it work and keep whatever you might have in the memories, when you power up the TS-830S.

Hi Chris,

I did this mod a couple years ago. Going from memory, I didn't cut any diodes, I just removed one end of each. I don't remember the specifics, but I believe I grouped and tied the open ends of the diodes and installed a DPDT mini toggle in such a way that I could turn the mod on and off. I was careful to make sure I could return the unit back to it's original state if the mod didn't go well, but never did because this has worked fine and I never had a problem with it.

I'm telling you what I did, but I'm not sure if it's really necessary. Once in a while, it does come in handy, but it would really suck if you damaged the unit. I use the vfo in it's original state a lot more than I do with the mod switched in. I would not want to do the mod if I couldn't switch it out.

Good Luck,
Kevin - N2FLP

Dave and Pete, thanks for your comments:

As much as I love my 830S, once I started listening to CW with my 500 Hz Collins/Yaesu filter mod (see files for details), and used the VBT to reduce the PB even more, I kept thinking that it sure would be nice to have a "FINE" tune option as the modern rigs employ.

Dave.yeah, the diode hack and chop really sounds like a butcher job. OTOH, done right, the VFO-230 has the electronics that would allow the slower tuning rate to be implemented. I wish I was better educated on the subject.

Pete. You're right on about the very high annoyance factor Kenwood built into the VFO-230 vis-a-vis the loss of all memories on shut down , etc. Since we know (or could reasonably assume) that Trio- KW must have had some very bright design engineers, it's hard to imagine how such a crappy design got through the inscrutable Japanese QC process. Go figure!

Anyway, I'm still hopeful that some bright guy/gal on this forum will come to the rescue with mods that will make the VFO-230 a pleasure to use.

Finished the cleanup yesterday. VFO dial is turning very smoothly. All static removed from the dials and switches. Still having some type of chugging/static at regular intervals. I don't receive this on other radios some I'm assuming either a realignment? If anyone has any suggestions on what may be causing this by all means please let me know. Here is a short video showing the issue:

So I cleaned the rest of the radio and reassembled the front plate and knobs. Static from all knobs is now Absent and the VFO knob turns very smooth. Unfortunately the static/noise is still an issue. Every revolution of the VFO the interference fades in then out as I keep turning and then repeats. I can receive some signals but very faint and far between. I know there should be plenty of chatter this time of night (7:30 - 8:00 pm EST).

If anyone has any suggestions on what the issue(s) may be by all means chime in. I'll see if I can make a short video so you can hear what I'm talking about.

Thanks,
Scott

Thanks Everyone for your help. Based on all of your comments, that the tubes were good, I went back and tuned the transceiver carefully on all bands into a dummy load. I believe I might have been doing the tuning wrong by adjust CAR control for mid-scale ALC reading when tuning in CW. By setting the CAR control so that the ALC reading is just within the ALC box I am getting 100 W on all bands in CW. For SSB, I adjusted the MIC control so that the ALC shows a mid-scale reading. With this I am getting 90-100 W on a peak reading Wattmeter. I think it is all good now.

Thanks again.

From: dr.intrepid@...
Topic: 55623 Message: 55623

Over the past few months my TS-820 seems to be losing power on transmit. When I tune up and transmit on a dummy load, external power meter is showing less than 80 watts, even with the Carrier maxed out. When I am transmitting on SSB, I my peak power is less than 40 watts, even with the mic gain maxed out.

Is it possible that my finals are tired? There is a tag on one of the 6146bs that they were replaced in 1996. I do not know the history of this rig. The service manual suggested that constant low power may be related to worn out finals.

On the air I am always told that I am light, but good voice quality.

Any suggestions?

Thanks,

David Richer, WB6VGO

David,
Tune-up is a good time to check your rig for maintenance requirements. Your Kenwood hybrid is an excellent tube tester, better than commercially made ones, in fact. It exercises the tubes under actual working conditions, and meters the results for you to observe.
- Notice how much drive is available. A fresh 12BY7A will provide more drive than necessary to swing the ALC Meter through its range, even on 10M. Low drive on any band shows that the driver tube is probably falling off in emission. It will continue to function for a while, but you might consider replacing it in the near future.
- Watch for falling drive level as the rig is keyed for a few seconds. A 12BY7A near the end of its life will fall off in drive within a few seconds or so of key-down. If you see your drive fall as you are watching, that tube is positively ready for retirement.
- Check the sharpness of the dip in CW Mode. A broad, shallow dip means the finals are nearing the end. You will notice reduced power output as well, most noticeable on the higher bands.
- Check for falling plate current under key down conditions. Just like the driver tube, final tubes at the end of their useful life will jump to full Ip and then quickly start falling off. When you spot this, they are ready for recycling. .

  The preceding was taken (copied & pasted) directly from Ken Kemski's web site k4eaa"dot"com which is a wealth of good KW hybrid info.
I am wondering about the phrase; " on the air, I'm always told that I'm light...but good audio." Have you ever asked what they mean? Since you stated that you do not know the history of the rig, have you done the basic alignment as stated in the operator/owner manual? You do not state if you are using a peak reading watt meter for you SSB observations...peak or averaging? How is your HV (high voltage) reading when rig is tuned up for max power?..you should see approx 750VDC or more...if the HV falls by more than about 10% between the "resting" value and what you see when the rig is tuned for full output....the HV caps are getting " voltage sag" and should be replaced. Also, I would check the values of R-5 & R-6 100 ohm 1/2watt and R-2 & R-3 10 ohm 1 watt for correct value. All 4 are on the final amplifier board, Also R-6 470 ohm which is on the Rectifier board
 73

55628. Hybrid Net Update (October 9, 2016)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-10-11 13:29:35 UTC
From: Mark Gilger
Topic: 55628 Message: 55628

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by Jimmy, WB2KNR. There
were 13 stations checking in under good band conditions.

We had the following number of radios checking in.

5 running TS-520(x)
3 running TS-530(x)
2 running TS-820(x)
1 running TS-830S
0 running TS-510
0 running TS-511
0 running TS-515
0 running 599 twins
0 running TS-900

Jimmy was running a TS-520 + Heathkit SB200.

The Sunday net was run by me, WB0IQK. There were
28 stations checking in fairly good band conditions.

We had the following number of radios checking in.

3 running TS-520(x)
0 running TS-530(x)
1 running TS-820(x)
4 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830s + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 ☐ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins

November 2015, Saturday net total = 66, Sunday total = 46
December 2015, Saturday net total = 55, Sunday total = 73
January 2016, Saturday net total = 129, Sunday total = 81
February 2016, Saturday net total = 98, Sunday total = 72
March 2016, Saturday net total = 74, Sunday total = 35
April 2016, Saturday net total = 101, Sunday total = 57
May 2016, Saturday net total = 51, Sunday total = 32
June 2016, Saturday net total = 39, Sunday total = 46
July 2016, Saturday net total = 52, Sunday total = 54
August 2016, Saturday net total = 28, Sunday total = 35
September 2016, Saturday net total = 64, Sunday total = 33
October 2016, Saturday net total = 26, Sunday total = 28 (Month to date)

55629. Help! New to Kenwood Hybrids

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-10-13 01:52:56 UTC
From: Bruce Braynard
Topic: 55629 Message: 55629

Just bought a real nice condition TS-520SE.
This radio puts out 150-155 watts PEP on 75, 40 and 20. About 135 on 15 and 110 on 10 meters.
Everywhere I read that 100-105 is normal for this radio.
Thought that maybe this radio had installed the "screen grid mod" so I pulled the top and bottom covers to check.
Upon inspection I do not believe the mod was done.
S2001a finals and not a spec of dust in the final cage
Just don't understand the high output.
I have four watt meters in line between the radio and the dummy load.Two Dentron WP1a, one Heathkit HM-2140, and one RF Applications P-3000 digital. Through this setup my Yaesu FT950 shows 105 PEP. My Kenwood TS930sat shows 125 PEP and my Drake C line shows 150.
Why is my TS-520se at 150-155 watts PEP.
Is this normal?
Thanks, Bruce N4JHY

55630. TS-520se output too high!?!!! Why???

Just bought a real nice condition TS-520SE. This is my first Kenwood Hybrid.

This radio puts out 150-155 watts PEP on 75, 40 and 20. About 135 on 15 and 110 on 10 meters.

Everywhere I read that 100-105 is normal for this radio.

Thought that maybe this radio had installed the "screen grid mod" so I pulled the top and bottom covers to check.

Upon inspection I do not believe the mod was done.

S2001a finals and not a spec of dust in the final cage

Just don't understand the high output.

I have four watt meters in line between the radio and the dummy load.
Two Dentron WP1a, one Heathkit HM-2140, and one RF Applications P-3000 digital.
Through this setup my Yaesu FT950 shows 105 PEP. My Kenwood TS930sat shows 125 PEP and my Drake C line shows 150.

Why is my TS-520se at 150-155 watts PEP.

Is this normal?

Thanks, Bruce N4JHY

The TS520 models, all 3 of them, are not designed nor can they produce that level of Peak RF output. If your Peak watt meter is displaying 155 watts output from your TS-520SE then your Peak watt meter is at fault.

Tuning the TS-520SE transmitter properly is not difficult but you should tune your TS-520SE into a 50 ohm dummy load.

The TS-520 models, all 3 of them, are rated at 160 watts DC input and 200 watts PEP input on side band. The typical output in CW mode is 96 watts. The IP meter should indicate 200ma and the HV meter (Red Scale) will indicate approximately 800 voltage (8 on the red scale). This indicates 160 watts DC input and the approximate CW output RF carrier is approximately 96 watts
.2 x 800 =160
The final amplifier in the TS-520 models operates in Class AB1 which has a typical maximum efficiency percentage of 60%. Therefore power output in CW mode is approximately 96 watts:
.6 x 160 = 96
A typical average watt meter output in side band with the transmitter tuned properly will indicate approximate 25 to 30 watts on peaks, a bit higher with a peak watt meter that's working properly but not over 100 watts output..

To determine if the so "QRO" wiring change has been done to your 520SE, simply measure the RF Unit's "210" and "300" pin voltages. If the 210 pin voltage is found to be approximately +255VDC and the 300 pin voltage is approximately +310VDC then the QRO wiring change mod has not been done.

You did not state whether you have the TS-520SE User manual, If you do not then you can download it along with the high resolution schematic for the TS-520SE with the links below.

What is the plate current at this rf output level in CW mode?

200ma is recommended max based on final tube plate dissipation rating and power transformer VA rating.

The radio is designed for 160 watts DC input for CW mode. At 60% efficiency would see approx 96 watts output. Assuming 800vdc plate voltage and 200ma plate current dc input power would be approx 160 watts. I have seen closer to 750 volts B+ on heavily loaded TS520 series rigs.

See 4.13 in your Operating Manual. Read the text and look at Table 4.

I forgot to mention. Better than "I dont believe" mod was done. How about measuring the SG voltage at the tube socket pins on the Final board.

Measurement is the best way to know for certain.

Hi Bruce,

I have a TS-520 (plain) which shows 125 watts out at 200 ma plate current (on CW). My manual says keep the plate current at 200 ma or less. I'm not sure how high it will load up, but I use the microphone gain control to keep the voice peaks well within the ALC range, resulting into 100 watts or less. And I use the the carrier level control to keep the power at 100 watts or less.

The difference between 100 watts and 150 watts is less than 2 dB - hardly worth stressing the power supply and PA amp components.

I guess there may be some stray reactance or some other problem somewhere in his setup. Cables, connectors or even a change of resistance in the dummy load, or other factors causing an error in the meter readings. My radio is Ham Radio...CW is Real Radio 73, John...K8JD

Thank you all for writing.
I have the new TS520se hooked up to my Heathkit SB230/GI7b converted amplifier.With the high output from the 520, in SSB mode, I am well over driving the amplifier.
I will try connecting the ALC line from the amplifier to the 520 and see what that does, and if not satisfactory will try the 9 volt battery and 250k pot hooked to the 520 ALC input to also try to lower the output to around 100 watts PEP.
It just seems strange that this radio has such high output!?!!??!
Thanks all again for your suggestions.

Hi Terry, and thanks for writing.

CW mode is no problem as the carrier control will let one adjust to an output level needed/wanted.

But, just like with my Drake T-4XC transmitter, when in SSB mode there is no output level control, and I like to be able to lean into the top of the alc indicated range, as I believe ALC is a form of speech processing. When I lower the mic gain, to lower output, I am told it sounds like i am under-driving the radio. May try hooking up the ALC line with my Heathkit SB230/GI7b converted amp. If that does not work well, may try the 9 volt battery with a 250k pot, hooked to the ALC input on the radio

I looked at, and ohm meter checked, the 100 ohm screen grid "stopper" resistors, and the 10 ohm cathode resistors.

I also checked screen voltage, both in receive mode and in xmit/no drive mode.

In receive mode it is 265 vdc and in xmit/idle it is 246 vdc.

I really should have keyed it down momentarily into my dummy load, but I was at the kitchen table when I had it open!?!!!!!!

I really like that regulated screen supply as seen on -

Just don't understand the high PEP output.

Bruce:

Yes you can use the CAR Level pot to produce the CW operating level that you want after loading to no more than 200ma in CW mode.

If you are loading to beyond 200ma you would not reduce the CAR Level pot during loading. You would close the plates of the Plate Load cap and readjust the Plate Tune cap for a peak in RF relative power or actual RF power on external wattmeter. During loading at 200ma Ip you should see no more than 100 watts output power and usually a little less on 10 meters.

Once properly loaded you would then switch to SSB mode and speak into the mic in normal voice level and adjust the mic gain for ALC indications to remain in the black printed range on voice peaks.

So from what you report we know is that the radio has not been "hot roddes" by the usual means of increasing the SG voltage to the Finals.

What we still dont know is how heavy you are loading in CW mode. To what Ip level?

Thanks to this usergroup I have learned how to correctly tune this nice TS520se up correctly.

The only other issue I have is with the speech processor.

When I operate the radio with the speech processor OFF, all is great with QSOs.

If I turn ON the speech processor, I have to click the T/R relay several times for the radio to have output. Many times there is only a few watts output, and 2-3 clicks of the T/R switch on the mic and the radio has normal outut.

If I go back to speech processor back OFF, all is fine.

Any ideas?

Thanks, Bruce N4JHY

I believe I misunderstood the tune up instructions for my new TS520SE.

They talk about the carrier control being set at half way up during the tune up procedure. That I did, and on the step where you would go from the driver peaking in the ALC meter position to dipping the plate in Tune/Plate current meter position, I then advanced to meter in RF position, function to cw and then adjusted the plate tune and antenna load for "maximum smoke". I paid no attention to the plate current, and from that point on 40 and 75 meters, observed 150-155 watts PEP output.

After reading several returns from you great guys on the usergroup I have changed the way I tune up my TS520se.

I have started tuning with the antenna load fully meshed and while keeping the plate tune at dip/max output, advanced the antenna load till 200 mills of plate current was seen.

At this level of plate current I see about 100-105 watts PEP out. This is a perfect level for my SB230/GI7b amplifier.

I am astounded that this radio will put out 155 watts PEP, but am sure running at that level would destroy the S2001a output tubes in short time.

I am also guessing that ALC is derived from the driver tube, not the finals. My thinking was that ALC was derived from the finals, and would hold the radio to a safe level. Now I see that that is wrong, and with the new tune up procedure all is good.

I love learning something new, and I sure did, with thanks from all on this great user group.

Thanks again to all.

Bruce N4JHY

Bruce:

You did exactly as your manual told you to do. Unfortunately the manual is not very well human factored. You needed to look at CW operation and Table 4 which follow some pages later. Professional procedure writers know that you never put a caution or a limit after a procedural step. If you do that you can easily end up with an "Aw Crap" moment!

Setting the CAR level pot to 1200 has nothing to do with final tube plate dissipation as at this step screen grid voltage is reduced to about 1/2 to allow time to get the tank tuned to resonance. CAR pot can be wide open. If meter pegs simply back down car level to get meter back on scale. None of the scales mean anything. Just tuning LC circuits in the Driver tube grid and plate to resonance to provide max RF drive voltage level. Not setting a level.

At this point setting CAR Level pot to 1200 is just a point to ensure that there is enough diode bias voltage supplied to the Balanced Modulator so it is unbalanced enough to provide sufficient carrier for the TIF amp to act upon and produce suffcient rf drive to the Transmit Mixer on the RF board and ultimately to the control grids of your S2001A final tubes.

ALC is not derived from the Driver tube. It is derived from the Control grids of the Final tubes anytime there is sufficient RF drive level on positive going peak of the envelope to make the grids positive with respect to the cathodes. This results in ua grid current flow which biases the ALC amp transistor which produces approx -1vdc to buck the ALC bus voltage and reduce the dc control or servo voltage to the TIF amp on the IF Board.
Go to my website k9tw.com and read about what ALC is and how it is derived.

Topic: 55644 Message: 55644

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by Jimmy, WB2KNR. There
were 16 stations checking in under good band conditions.

We had the following number of radios checking in.

4 running TS-520(x)
3 running TS-530(x)
1 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running TS-515
0 running 599 twins
0 running TS-900

Jimmy was running a TS-520 + Heathkit SB200.

The Sunday net was run by me, WB0IQK. There were
11 stations checking in fairly good band conditions.

We had the following number of radios checking in.

3 running TS-520(x)
2 running TS-530(x)
1 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830s + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:

I forgot to comment on the switch tab.

If you are careful, use a small amount of glue, you can glue the switch tab onto the switch. I've done that with good success.
Do not use "Gorilla" glue!! Gorilla glue expands as it dries and it can spread to the front panel making the switch unusable.

You can purchase a new INRAD CW filter for your TS-520SE
http://www.inrad.net/product.php?productid=185&cat=50&page=1
The INRAD filter is square and slightly larger than the Kenwood filter. It will not slide right into place in the space on the IF board. You have to use care when installing the filter otherwise you can break the diode switch diode lead next to the space provided for the CW filter.
You also have to change the filter wiring, see the TS-520SE user manual for instructions to install filters.
If you do not have the TS-520SE user manual, you can download it from my website
http://w5rkl.com/wp-content/uploads/2014/04/TS-520SE-Instruction-Manual.pdf

The file size is 21meg and it is in pdf format.
CW filter installation instructions are found on page 32 of the TS-520SE user manual.
The INRAD CW filter is excellent, has a bandwidth of 400Hz. I've installed the CW filter in a TS-520S. If you purchase the INRAD filter, take your time installing the filter.

Date: 2016-10-17 18:31:16 UTC
From: Mike W5RKL
Topic: 55647 Message: 55647

I'm in need of a few 2SC460(B) transistors to repair a TS-520 CAR Unit board, Q2 buffer amp failed. I know the NTE85 is a cross for the 2SC460(B), I have tried an NTE85 and it works in the CAR Unit board as Q2 but the current level is twice as high, 25ma with an NTE85 verse 11.4ma with a 2SC460(B).

If you have any 2SC460(B), drop me a line off group with price.

Mike;

How many do you actually need?

I have 7 of them but, since I work on some of these old beasts I do need to keep some on hand.

I'll be glad to share.

Hi Mark,
Here is what I have learned about Japanese transistor part numbers such as the 2SC460(B) verses the 2SC460.

The transistor part number is divided up into 5 elements
2 | S | C | 460 | B |

The number "2" is element 1 which indicates the number of active internal or external elements minus 1.

The letter "S" is element 2 which originally indicated this device has been registered with EIAJ. It appears this is no longer the case. The abbreviation "EIAJ" stands for "Electronic Industry Association of Japan".
The letter "C" is element 3 which indicates polarity and application. The "C" in this case indicates "NPN" and the application is "High Frequency".
The number "460" is element 4 which is the serial number in order of registration.
The letter "B" in parenthesis is element 5 which is the suffix indicating improvements and their sequence. The "B" suffix indicates the "second improvement" in the 2SC460 transistor series.

The above information was obtained from Wagner Electronics's semiconductor documentation which is available on my website in pdf format. Click the following link to download the document.
http://w5rkl.com/wp-content/uploads/2015/02/01-Semiconductor-data.pdf
There are other websites that provide additional information concerning solid state component part number break downs, you just have to spend time looking/searching for them on the web.

55655. TS-820: no drive and no output

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-10-18 16:31:59 UTC
From: phil.erickson@...
Topic: 55655 Message: 55655

Hi all,

Here's an update. Joe and others helped get me started on my project level TS-820 with unknown history. The good news is that the receiver and calibrators work fine and with an alignment, will likely be in fine shape.

However, the rig does not transmit on any band and I'm suspecting no drive:

- The T/R relay works OK.
- The Bias control on the back does have an effect and with MODE switch in USB as per the operations manual, I do get 60 mA for Ip on the meter with a mid-range value on the Bias. According to K9TW's pages, this likely indicates that the 6146 finals have the correct resting plate current.
- I have 850 V or so in the HV meter position when I'm in SEND mode so the plates are definitely getting current and the HV caps are OK.
- However, in the TUNE position and with meter on ALC, I do not get any needle movement (i.e. no ALC) on any band no matter the position of the DRIVE control. I'm following the K4EAA tuning procedure first paragraph at

http://www.k4eaa.com/tune-up.htm http://www.k4eaa.com/tune-up.htm

- I've pulled and manually inspected the 12BY7A tube (it looked good, for what that's worth) and resocketed it with no results. I also reseated the RF1, RF2 and RF3 connectors going to/from the RF board with no results.

I think the next step is to use a scope to see whether it is a mixer problem or driver problem using the RF trace chart at

http://www.k4eaa.com/820T_level.jpg http://www.k4eaa.com/820T_level.jpg

but before that, does anyone have any other simpler things to check first?

Also, I notice K9TW has a TS-830S driver stage testing document at

https://drive.google.com/file/d/0B5NBmwIA2pskRVo4dlB2RWxIdE0/view
https://drive.google.com/file/d/0B5NBmwIA2pskRVo4dlB2RWxIdE0/view

but any modifications to the specific test points and voltages listed there for the TS-820?

I really appreciate the terrific help!

Phil W1PJE

Mark:

If you download the Hitachi data sheet for the 2SC460 you will see near the end of the electrical characteristics just before the graphs a table that lists the Transfer Admittance Characteristics for the 2SC460A, 2SC460B, and 2SC460C devices. There are 4 admittance characteristics listed here with values for differing operating frequencies.

These Y-parameters are used by RF design engineers when designing transistor RF amplifiers (especially useful for high frequency applications) to design impedance matching networks, to determine gain, to determine stability (very important) etc.

Not so much concern for us with our application as a Buffer amp on the Carrier Oscillator board.

The only parameter that has much difference between the A,B, and C versions is the Input Admittance Yie. If you look at 10.7mhz values you will see the following:

2sc460A = 0.91 + j 2.0
2sc460B = 0.61 + J1.9
2sc460C = 0.39 + J1.3

These values are Y= G +/- jB. Where G is conductance which is the reciprocal of resistance and B is susceptance which is the reciprocal of reactance. G use to be expressed in Mho, but was changed to Siemans. The units above are mS or millisiemans.

So it looks to me like KW engineers just speced the "B" device as the middle of the road.

I would not hesitate to substitute any one of the three devices especially in the Carrier Osc application where the configuration is Emitter Follower and frequency is under 4 mhz.

If you really want to get into this more deeply read up on Transistors as a Two-port "Black Box". Be prepared to get a head ache or take a nap!

Did you turn the SG switch off and try peaking the Drive in CW mode? If you get ALC indication you know that the Driver stage is good, operating bias is available and set properly, and the Final tubes have cathode emission.

Likely have lost the R5/R6 56k ohm screen grid divider resistors that cut the Screen grid voltage approx in half in Tune mode to give you time to adjust the Tank circuit to resonance ie make that initial Plate Current dip.

Best to replace both R5 and R6 even if you find only one has gone very high or infinite.

Terry K9TW

Hi Terry,

I was hoping you would reply!

In CW mode with SG off and VCO to 250, I still do not get any ALC action at all no matter what the band or what the DRIVE signal is set to.

I followed your driver stage document and got the following (results given for 7.25 MHz, but it's the same on all the bands):

1) Control grid pin 5 on the finals: -100 V DC in RX mode, -62 V DC in TX mode. These levels seem OK. But AC waveform is unstable in frequency and peaks at only +/- 330 mV amplitude with DRIVE at about 13:00 position.

NB: above 14 MHz, I cannot peak DRIVE as I run out of room fully CW.

This so far sounds like I do indeed have no drive.

2) Driver tube: all DC voltages look OK according to the schematic values. But at Pin 2 (input to driver tube from TX mixer output), I can only find a < 15 mV AC signal there and it looks ratty.

3) TIF input signal on the RX board (RF1 connector pin 10): I don't know what these are supposed to look like, so I took two photos.

1st photo = in RCV mode. DC level = -2.43 V.
https://www.dropbox.com/s/8qj4nha854vo6qr/tif_receive.jpg?dl=0
https://www.dropbox.com/s/8qj4nha854vo6qr/tif_receive.jpg?dl=0

2nd photo = in SEND mode. DC level = 0.4 V.
https://www.dropbox.com/s/7k0s1a6da8qkg3k/tif_send.jpg?dl=0
https://www.dropbox.com/s/7k0s1a6da8qkg3k/tif_send.jpg?dl=0

The main question: is the problem still on the RF board, or is that TIF signal not right and I am now back to the IF board (hopefully not)? How to troubleshoot further?

Thanks very very much

Phil W1PJE

In CW mode with SG off and VCO to 250, I still do not get any ALC action at all no matter what the band or what the DRIVE signal is set to.
I followed your driver stage document and got the following (results given for 7.25 MHz, but it's the same on all the bands):

NB: above 14 MHz, I cannot peak DRIVE as I run out of room fully CW.
This so far sounds like I do indeed have no drive.

Phil:

TIF at RF-1 Pin 10 should be approx 38mv rms rf volts or approx 107mv P-P rf volts. Can take on 40 meters around 7.150 if your scope is loading down 14mhz measurements. On 40 can see as much as 140mv P-P. It will be dirty as there will be VCO oscillator leak back. If your scope has a digital filter mode set it up for Low Pass filter with cutoff at 10mhz and should get a cleaner and more stable sine wave to sync to.

You dont have to read the RF drive at Pin 2 of Driver tube. Easier to get on air variable cap VC-1 solder lug "S" which is electrically MD (S is the small set of plates). Should see approx 1.5 to 2.5 rms rf volts or approx 7v P-P which is the output of the TX Mixer. With no or very low TIF of course wont see any output from the TX Mixer.

If you have good TIF and no output from TX Mixer at MD then make sure you have VCO signal at RF-1 Pin 4 and at TP on RF board. Should see approx 800 to 900mv rms VCO level.

Do you have a CW filter installed? If so, try adjusting the CAR-2 8830.700 TC-1 trimmer. Dont set it with Freq counter just try adjusting it thru its range to see if get some drive. Sometimes the CW filter is bad and has lots of attenuation or Fc has shifted high or low. Can also bypass the filter with a .01 to .047 uf cap across the CW filter to see if you then have good TIF.

Hi Terry,

I was hoping you would reply!

In CW mode with SG off and VCO to 250, I still do not get any ALC action at all no matter what the band or what the DRIVE signal is set to.

I followed your driver stage document and got the following (results given for 7.25 MHz, but it's the same on all the bands):

1) Control grid pin 5 on the finals: -100 V DC in RX mode, -62 V DC in TX mode. These levels seem OK. But AC waveform is unstable in frequency and peaks at only +/- 330 mV amplitude with DRIVE at about 13:00 position.

NB: above 14 MHz, I cannot peak DRIVE as I run out of room fully CW.

This so far sounds like I do indeed have no drive.

2) Driver tube: all DC voltages look OK according to the schematic values. But at Pin 2 (input to driver tube from TX mixer output), I can only find a < 15 mV AC signal there and it looks ratty.

3) TIF input signal on the RX board (RF1 connector pin 10): I don't know what these are supposed to look like, so I took two photos.

1st photo = in RCV mode. DC level = -2.43 V.
https://www.dropbox.com/s/8qj4nha854vo6qr/tif_receive.jpg?dl=0
https://www.dropbox.com/s/8qj4nha854vo6qr/tif_receive.jpg?dl=0

2nd photo = in SEND mode. DC level = 0.4 V.
https://www.dropbox.com/s/7k0s1a6da8qkg3k/tif_send.jpg?dl=0
https://www.dropbox.com/s/7k0s1a6da8qkg3k/tif_send.jpg?dl=0

The main question: is the problem still on the RF board, or is that TIF signal not right and I am now back to the IF board (hopefully not)? How to troubleshoot further?

Thanks very very much

Phil W1PJE

Phil:

The other thing I forgot to mention is that instead of jumpering across your CW filter you can also see if you have RF drive in SSB mode (SG switch off).

Connect mic and set mic gain to 1200. Flip to Send and whistle into the mic and see if you then have ALC indication. Wont be able to peak the ALC indication unless you are good a holding a sustained note.

Better to inject 1200 hz @ 5mv audio into mic line, but whistling will show that you do have TIF signal, TX mixer output, Driver tube output, and RF drive at control grids of the Finals.

Just a quick test to see if rig is capable of producing RF drive.

If this works suggest you measure Carrier level at input of CW filter and at output. You can do that at D7 and D8 switching diodes. Should see approx 60mv rms at D7 and 25mv rms at D8. The delta is the filter insertion loss.

I pulled the NTE85 from the CAR board and replaced it with a 2N3904. The board works and the current level does decrease to 16ma with none of the MODE pins (CWT, USB, or LSB) selected, increasing to 19ma selecting any of the MODE pins. This is a reduction of 6ma.
I emulate the MODE switch during board testing by using a short alligator clip jumper wire connecting +9VDC to the individual MODE pins (CWT, USB, or LSB).
Having a bad board as a test platform works great.
What symptoms will occur when the CAR Unit board fails?
When the CAR Unit board fails, whether Q1 oscillator or Q2 buffer amp fail, the 520 will not have any TX drive and RX will also significantly degrade.

The CAR Unit frequency is the RX BFO signal applied to the GENERATOR board's "balanced detector". The BFO signal mixes with the IF signal resulting in a Difference output which is the recovered side band audio or the beat frequency in CW. The "balance detector" is the receier's "product detector" which is located on the GENERATOR board. A produce detector requires 2 signals, the IF and BFO. If one signal is missing then the product detector output will be significantly degraded indicating a failed receive.

The CAR Unit frequency is the TX base RF signal that is used for both CW and side band (TUNE mode is also included). The CAR board provides the initial RF signal applied to the balance modulator on the GENERATOR board. This signal, in side band, mixes with the Speech amp output to produce the DSSC (Double Side Band Suppressed Carrier) output to the IF Unit where it mixes with the VFO 5Mhz signal in the VFO mixer to produce the 8Mhz variable TIF signal. In CW mode, TUNE mode also, the CAR control on the front panel applies a variable DC voltage to the GENERATOR board's balance modulator. The variable DC voltage "unbalances" the balance modulator allowing the CAR board's signal to be applied to the IF Unit's "VFO Mixer" where it mixes with the VFO signal producing the 8Mhz variable TIF signal to the RF board. The 8Mhz TIF signal mixes with the band switch selected HET OSC crystal frequency to produce the operating TX frequency applied to the driver and ultimately to the final tubes. Missing CAR board signal results in loss of ALC drive and ultimately no TX RF output.
A scope connected to the GENERATOR board's "CAR" terminal and GND will indicate the presence of the CAR board's signal. The CAR board's signal output level can vary between 800mv and 1 volt.

All of this can be seen by studying the 520 block and schematic diagrams found in the TS-520 model user and service manuals.

Hi Mark,

Here is what I have learned about Japanese transistor part numbers suchas the 2SC460(B) verses the 2SC460.

The transistor part number is divided up into 5 elements

2 | S | C | 460 | B |

The number "2" is element 1 which indicates the number ofactive internal or external elements minus 1.

The letter "S" is element 2 which originally indicated thisdevice has been registered with EIAJ. It appears this is no longer thecase. The abbreviation "EIAJ" stands for "ElectronicIndustry Association of Japan".

The letter "C" is element 3 which indicates polarity andapplication. The "C" in this case indicates "NPN" andthe application is "High Frequency".

The number "460" is element 4 which is the serial number inorder of registration.

The letter "B" in parenthesis is element 5 which is the suffixindicating improvements and their sequence. The "B" suffixindicates the "second improvement" in the 2SC460 transistorseries.

The above information was obtained from Wagner Electronics'ssemiconductor documentation which is available on my website inpdf format. Click the following link to download the document.

http://w5rkl.com/wp-content/uploads/2015/02/01-Semiconductor-data.pdf

There are other websites that provide additional information concerningsolid state component part number break
Mike,
Ceitron has the 2SC460, but not the (B). Not sure if the 'B' is
important or not. They have them listed for $.25 each, but there is a
$25 minimum order.

Topic: 55655 Message: 55663

Hi Terry,

As suggested, I checked TIF at RF-1 pin 10. Mode=CW, CAR set full CW, SG switch off, VFO = 250, 7 MHz band (I meant it to be 7.150 MHz, but this should not matter much). No LPF available on this scope but set averaging=16 to get a decent waveform, in this image:

https://www.dropbox.com/s/uvn8ac92qjh5a65/tif_rf1_pin10.jpg?dl=0
https://www.dropbox.com/s/uvn8ac92qjh5a65/tif_rf1_pin10.jpg?dl=0

RF amplitude = only about 20 mV P-P (tiny). Does that look wrong to you too?

Second check is at solder lug for VG-1 small plates as suggested (TX mixer output). Got this:

https://www.dropbox.com/s/vpedzrmtp2s51fq/tif_at_vc1.jpg?dl=0
https://www.dropbox.com/s/vpedzrmtp2s51fq/tif_at_vc1.jpg?dl=0

Even lower amplitude (11 mV P-P). So the TX mixer isn't producing anything probably because TIF is not big enough.

Finally, checked VCO at RF1 pin 4 and it seems to be OK amplitude (nearly 2 V P-P; maybe a little low at ~690 mV RMS):

https://www.dropbox.com/s/06mxhvzt6q83i2m/vco_rf1_pin4.jpg?dl=0
https://www.dropbox.com/s/06mxhvzt6q83i2m/vco_rf1_pin4.jpg?dl=0
Note that all these images have averaging=16 on to clarify the signal.

So I'm guessing I have bad TIF coming from the IF board and that the RF mixer, driver might be OK. I do not have the CW filter (only SSB) so that wouldn't mess TIF up in CW mode.

Can you confirm my conclusions, and what would you suggest at this point? I won't be able to resume debugging for a couple days but I certainly appreciate the help!

OK then not getting anything at output of the BM either with CAR Level pot or with Audio input.

Need to confirm that you have Carrier (LO) in to the BM. Need to see if you have Carrier at CA2 on IF Molex Conn IF-5 Pin 13. Molex connectors are problem on the 820 series. Can have bad molex pin soldering, cracked trace, bad crimp connection on lead wire, and/or broken crimp terminal floating inside the connector body (broken off spring temper contact wedge). Can measure at TP-5 on IF board first and if not there then measure at Conn IF-5.

Carrier at TP-5 should be 300mv rms or 800mv P-P plus.

If you have Carrier at TP-5 then go to D5 switching diode at SSB filter and should see approx 150mv rms RF or 400mv P-P there with Car Level Pot at 1200.

If you have good signal levels then next thing is go to IF-3 and see if you have good ALC bus voltage on AGL. If not then first place to look is at Aux Control relay on bottom center of radio. It is MH4P Omron. Need to pull it and measure and clean contacts. If no ALC bus voltage at AGL then Q1 TIF amp wont be turned on.

Your 10 to 11 meg meter will pull it down from RF-1 level. Maybe under 3vdc depending on where you have set RF-1 reference voltage. I normally set for 3.5vdc.

Phil:

I forgot to ask----did you perform alignment which includes adjusting the Carrier Osc levels?

If so, did you set to 50mv rms level as directed by the Service Manual?

If so, that is wrong. The Product Detector and BM are diode mixers and wont work properly with a 50mv Local Oscillator (LO) level.

The TS820 Service manual errors have been discussed many times here. Sadly too often wrong test point, wrong adjustment device, and wrong acceptance criteria called out. It is one area where KW dropped the ball and it goes well beyond grammar and translation induced errors.

Suspect the work was contracted out with no oversight of contractors. Dont know for certain but easy way for this to have happened and not as prevalent in other Hybrid models documentation.

Look at the Carrier Osc schematic and you will see the standard 0.3v rms level called out.

Hi Terry,

I'll go back through and make sure that I follow the schematic suggestions for proper Carrier Osc levels. I am somewhat new to all of this discussion so I don't have the details of the wrong 820 alignment information at my fingertips, but hopefully I can follow the schematic as the right reference (unless you tell me there are bad errors there too).

Are the TX and RX level troubleshooting diagrams OK, or do they have errors as well? I'm thinking for example of

Yes TX Level Diagram is OK.

However, you will need some experience running them to recognize instrument effects and what happens when you have a bad bandswitch contact and not switching in the required parallel resonant circuit in to the grid or plate circuit. If you have trouble running on 14 mhz OK to run on 7 mhz.

Dont worry about running RX level diagrams at this time. The levels listed are not levels that you would measure. They are levels you would inject to obtain a specific amount of audio output voltage. See my website for a primer on how to run RX level diagram.

When you adjust T1 to set CA2 carrier level to 300mv (not 50mv) at TP-5 make sure after finding the peak rf voltage that you adjust the orange ferrite core ccw direction to arrive at 300mv rms volts.

Like all oscillators there will be a fast and slow side to the response curve. To understand why need to study resonance and what response curve looks like on inductive side of resonance vs the capacitive side of resonance. The db/octave rate of change is different on the inductive side of resonance as compared to the capacitive side of resonance. One has a linear relationship and the other an inverse relationship. The service manual gives no precaution or direction on how to turn the core.

Not good idea to set the RF voltage on the peak or the fast side of resonance as the oscillator might not start reliably each time you flip to Send.

Hi Terry,

I believe I have traced the problem to the D5 high speed switching diode on the IF board, part of the input circuit to the SSB filter. This is surprising to me. Perhaps you can confirm:

First, I have a good CA2 signal at TP-5, and a good AGL level at IF-3 pin 6 (3.15 V, same as RF1). [But how do you adjust VR2 though on the AF-AVR board to get RF1 up to ~3.5 V since the pots are right up against connectors? Do you use a special right angle tool or something? Perhaps you need to remove the board but then I don't see how you can adjust with power applied. This is why I left RF1 at 3.15 V for now.]

At the D5 cathode, I have a nice 674 mV P-P (238 mV RMS) incoming signal when I switch to SEND in TUNE mode. DC level = 2.18 V.

But at the D5 anode, I get no signal at all - DC or AC. So I'm guessing the switching diode has failed, since this with R5, C12, and C10 form the input network for the SSB crystal filter. Since the filter eventually feeds the IF amp, no wonder I was not getting any signal to the driver and finals. The solder joint looks quite good on the D5 anode, so I'm assuming it is dead.

Any caveats in replacing it? An old message here says to use a NTE-177 rather than the original 1S1587 but is that still right? Or am I fooling myself and something else is wrong?

Thanks as always -

Phil W1PJE

Topic: 55655 Message: 55673

Hi again,

Perhaps I was too hasty. Upon rereading the schematic, I see that D5 is oriented such that it has to have a voltage bigger than ~3V on its anode to switch on and let the signal through. So now my thought is that perhaps the MODE switch is screwed up and I'm not passing along the proper control voltage through SSB/SSF/SSC on IF-2 connector to turn on D5 and D6 and therefore complete the signal path. I'll move to checking those voltages next. Does this ring any bells?

I should have recognized this before, as the one major problem with this radio that leapt out immediately is that the MODE switch does not snap between positions and is very 'mushy'. I've been dealing with it, but it feels as if the spring and ball bearings that provide the snap are broken or not functioning correctly. I was hoping not to replace this one as it has a lot of lines and 6 switch wafers, but perhaps I don't have a choice given my current symptoms. I have no idea whether this part is still available though.

Look at the filter diode bias voltage divider resistors. They are different values.

As I recall about 3vdc is correct on input side of filter and 9vdc is correct on output side of filter. If turned on will read close to same voltage on cathode and anode. Just less than the barrier voltage . About 0.6vdc lower.

Try jumpering from one diode to the other with .01 to .047 uf cap (value not critical) and see if you then have good RF drive. If you do then couple of possibilities.

1. Bad switching diode
2. Missing or insufficient forward bias
3. Bad filter
4. Bad solder connections at filter pins

If no RF drive after bypassing the SSB filter go to TIF output at molex connector on IF board to see if it is there. If it is then go to RF board molex connector at RF-1 and see if there. Common to have bad molex connections at either end.

If after bypassing filter no TIF at output of IF board then work backwards toward last place you saw good Carrier. At D24 should have about 900mv. Hard to get on wiper of VR-5. Can read on two of the BM diodes and should see approx half of what your read at D24. Can get on Q1 leads and D44.

Phil:

If it turns out that you have a bad 1S1587 switching diode I would NOT use a NTE177 diode to replace it. The 1S1587 diode has a very fast reverse recovery speed (2ns). The NTE and ECG generic subs can have up to a max of 50ns. I would try to find a NOS 1S1587 or ask Walter Dilley if he can harvest a couple for you. Absent that I would use a 1N4148 fast switcher which has reverse recovery of approx 4ns.

Reverse recovery is the time it takes for the diode to switch from minimum IF filter rf signal insertion attenuation to maximum filter isolation. Would be more important to you if you had a CW filter installed. Fast switching is designed to prevent getting in a state where both the SSB and CW filters present a RF signal path for a moment.

This was addressed by KW in the TS830 design where two different types of filter switching diodes are used.

Hopefully, a 1S1587 has not failed which is not very common.

Please dont change the filter switching diodes based on a hunch. Always try to measure as you have been doing. Recognize that not always easy to get on the cathodes and anodes due to component density and flush mounting.

Hi Terry,

I spent a bit more time with the rig earlier today and noticed that I had a good RF signal at both D5 and D7's cathode. The D7 diode is at the input to the CW filter.

But as I mentioned before, the CW filter is missing and based on the solder marks on the board, someone obviously removed it rather clumsily. They did not leave a jumper between the trace pads where the CW crystal filter was. From the signal path on the IF schematic, this seems to me to break the signal chain in those modes (C16 and C17 route the RF to ground and there would be no connection between C14 and C15).

I took a clip lead and carefully touched it to the two terminals where the CW filter would be. In TUNE mode, I then finally got plenty of ALC swing - in fact, with the DRIVE control, I could mostly only cycle between nearly zero ALC and a pegged meter. I'll figure that out later.

So before I move to the next stage of investigations, should there have been a jumper across the missing CW filter terminals or would that screw something up? I'll install one unless this will do something unwanted. From my schematic reading, I think that's probably what is needed.

I'm beginning to understand this radio's design a little better.

Phil:

NO---There should be no jumper in place of the CW filter???

Where do you have the IF board Molex Conn IF2 Plug? It has 3 positions. With no CW filter installed it should be in the "A" position. If in B or C diode bias is supplied to D7/D8 in Tune and CW modes. No CW filter = no carrier to TIF amp.

However, I asked you to perform ALC test in SSB mode. You reported back that with rig in LSB or USB and mic gain at 1200 you whistled into the mic and had no ALC indication when flipped to Send. In that config makes no difference where you have the IF2 plug. The SSB filter diodes should be biased on in all 3 plug positions. Perhaps you have more than one problem. Perhaps a bad mic or mic amp circuit not functioning?

Try the test again without the Mic connected to the front panel mic jack. Rig on, heaters on, sg switch off, mic gain 1200 or greater, meter ALC 40 meters, VFO 7.150, Drive 1200, mode switch LSB/USB, Flip to Send and take finger and touch the bottom right mic pin in the jack. Should be able to get very strong ALC indication if there is carrier at D5 and D5/D6 are both good and being biased on by SSB from Molex Conn IF-2.

Good Carrier at D5 and D7 in Tune and CW is fine. The question is what do you have at D6/D8 cathodes. No Carrier there means nothing thru the SSB filter. By jumpering the CW filter you proved that Q1 TIF amp is working, there is TIF output at IF Board molex, there is TIF at RF board molex, etc etc etc etc. The question is: Why no ALC indication in TUNE or CW when applying Carrier to D5 at input of SSB filter? I gave you several fault possibilities that included no 14vdc at SSB IF2 molex, no or low diode bias at D5/D6, bad IF filter.

At no time did I tell you to place jumper across the CW in and out PC pads. I told you more than once to jumper the SSB filter.

Jumpering the not in place CW filter doesnt add anything to understanding of how the radio works.

I have exhausted any value I can add.

Have fun.

My YO-901 started humming like a 60Hz hum when "perhaps" I put too much RF power through it... changed up antennas to a new balanced line doublet, and by mistake ran a bit high power through the thing... probably about 300 watts...

Any idea where to start? I am thinking a capacitor might have blown...

Any and all thoughts on this welcome...

Paul

What rear panel connector do you use, ANTENNA or EXCITER?

The ANTENNA connector has a power rating of 500 watts
The EXCITER connector has a power rating of 100 watts

You say you hear "hum". Are you hearing hum from the power transformer
or seeing hum on the display?

It's quite possible one or more of the power supply filter capacitors
have failed. You can see the filter capacitors on the main YO-901
schematic found at the end of the user manual. If you do not have the
YO-901 manual then you should download it at:

www.foxtango.org/ft-library/FT-Library/FT101ZD-901-902/*YO-901*.pdf

You also might try the Fox Tango Group, they may have additional help.

If the link I provided to the YO-901 manual doesn't work try
highlighting the entire link, right click, select "copy" then move your
mouse over your browser's address box, right click and select "paste and
go" into your browser address box. The browser should go to that address
and download the file to your computer.

If that still doesn't work, click on the following link, it will do the
same thing, download the YO901 manual to your computer.

Phil:

Please do the following:

1. Place the IF-2 Plug in the A position. See the Service Manual under Section 6 installing CW filters for the orientation.
2. Measure the dc voltage at "SSB" pc foil pad on the IF board. Easy to see with mini-mag or similar light and access with your DMM. Should be approx 13 vdc in Tune, CW, and SSB modes. Can also access it by prodding down inside IF-2 plug, but that doesnt mean it is making it to the SSB PC pad. There is a reason I advise as I do.
3. If you have 13vdc at SSB on the pc solder pad, try peaking the ALC in Tune and CW modes. If no go need to measure the diode bias voltage at D5 and D6. I now I have previously provided these voltage levels. D5 will be in 9.5vdc range and D6 will be in 2.5vdc range. Measure on the cathodes and the anodes. May have to prod with small sharp tipped probe at R6 and R9. I use a hobby floral arrangement pin and mini-grabber or a SMT meter probe. The voltage at the cathode of D5 and D6 will be approx 0.2vdc to 0.3vdc lower than what you read at the anodes if the diodes are turned on.

Disregard all other previous advice from me.

55686. Hybrid Net Update (October 23, 2016)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-10-23 22:27:06 UTC
From: Mark Gilger
Topic: 55686 Message: 55686

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by Jimmy, WB2KNR. There
were 8 stations checking in under fair band conditions.

We had the following number of radios checking in.

4 running TS-520(x)
2 running TS-530(x)
1 running TS-820(x)
1 running TS-830S
0 running TS-510
0 running TS-511
0 running TS-515
0 running 599 twins
0 running TS-900

Jimmy was running a TS-520 + Heathkit SB200.

The Sunday net was run by me, WB0IQK. There were
15 stations checking in fairly good band conditions.

We had the following number of radios checking in.

5 running TS-520(x)
2 running TS-530(x)
0 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my Heathkit SB202/401 combo + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 ☐ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins

November 2015, Saturday net total = 66, Sunday total = 46
December 2015, Saturday net total = 55, Sunday total = 73
January 2016, Saturday net total = 129, Sunday total = 81
February 2016, Saturday net total = 98, Sunday total = 72
March 2016, Saturday net total = 74, Sunday total = 35
April 2016, Saturday net total = 101, Sunday total = 57
May 2016, Saturday net total = 51, Sunday total = 32
June 2016, Saturday net total = 39, Sunday total = 46
July 2016, Saturday net total = 52, Sunday total = 54
August 2016, Saturday net total = 28, Sunday total = 35
September 2016, Saturday net total = 64, Sunday total = 33
October 2016, Saturday net total = 50, Sunday total = 54 (Month to date)

Hi boy do I have a problem. My receiver was working normally then I could only receive very strong signals. Figured it must be in the RF stage on the R F Board. I removed D1 and L41 and found them to not be shorted or burned. I ordered Q1 and white I waited removed the wafer switches one at a time and soldered a small wire from the trace to the end of the contact terminal. You know the problem about the rivet to contact and trace loosing continuity.

Received Q1 and put everything back together and now the revive is DEAD.

Anyone have a troubleshooting method for this board? Signal injection points or other suggestions?

Hi Terry,

1) IF-2 is now in "A" position.
2) SSB pc foil pad reads 13.1 V in TUNE, CW, and SSB modes.
3) ALC still does nothing in TUNE and CW modes.

The rest is done at 14.175 MHz in TUNE mode in case it matters, SG switch off, CAR to 1200 position:

4) At D5 cathode, DC level = 2.15V in receive, 2.08V in send. Send has RF on it at the ~100 mV P-P level.
5) At D5 anode, DC level = 2.55V in receive, 2.50V in send. No RF signal detected in send.
6) At D6 cathode, DC level = 9.70V in receive, 9.50V in send. No RF signal detected in send.
7) At D6 anode, DC level = 10.0V in receive, 9.80V in send. No RF signal detected in send.

I have double checked these results.

OK---do the subtractions. D5 anode - D5 cathode dc voltage. Do same for D6. If you do the subtractions in Rx mode can see how hard diodes turned on and I assume that you do have path thru the SSB filter in receive mode at this diode biasing level?

In TX mode flipped to Send you have at least that much voltage drop if not more than what you see in Rx mode. Ideally in Tx mode would like to see about 0.5 to 0.6vdc difference (cathode voltage lower than anode voltage) to really turn the diodes on hard.

100mv rf at D5 cathode is good, but when you forward bias D5 on in TX mode you see no RF at the Anode. What RF level do you still see at Cathode of D5 when you flip to Send? Does it stay at 100mv?

Did you try jumpering from D5 cathode to D6 cathode in Tune and CW send?

Sorry---- It has been a very long day and spoke too soon. I see you reported 100mv rf carrier at Cathode of D5 when flipped to Send and nothing at the Anode of D5. If that is true then D5 cant be turned on in Tx mode. Should see nearly the same RF level at Cathode and Anode.

By the dc voltage you report it looks to me like you have sufficient bias to be turning D5 and D6 on to some degree when flipped to Send in Tune or CW modes and they have to be turned on in Rx mode allowing the RIF signal to pass thru the IF filter if the Receiver is working as I assume it is? Can you hear the Marker signal or copy off air signals?

Hi Terry,

I really appreciate continuing this thread despite a long day on your end.

Yes, on initial testing the receiver seemed to work well. I could hear the calibrator/marker and I copied at least one USB signal on 20 meters using an external antenna. I did not perform quantitative sensitivity tests yet though.

The forward drop across D5 is ~0.3 to 0.4 V as you can see from my measurements whether in receive or send mode, yet the RF signal seems not to make it through the diode in Send. D6 has the same forward bias.

Looking at the circuit, either this drop is not enough to turn the diode sufficiently on in Send and therefore the DC biasing is now not correct due to problems with R5, R6, R7, R8, and/or R9. Or the diode itself is not functioning correctly.

Note that I have not yet tried jumpering from D5 cathode to D6 cathode and bypassing the whole SSB filter section. I ran out of time today.

Phil:

If you have enough forward bias to get that very low level RIF thru the SSB filter then when flipped to Send the diodes and divider resistors cant be the problem. I say this as you report similar levels of forward bias in Rx and Tx modes and remember diodes dont turn on like snap action mechanical contacts. As previously mentioned would be nice to see approx 0.5 to 0.6 vdc, but at 0.3vdc the diodes will be conducting sufficiently for RF signals to pass.

The reason I wanted you to jumper the SSB filter is because you are relying on ALC indication to tell you that the Carrier from the BM is being applied to the TIF amp. If the 14mhz Mixer and/or Drive coils are not properly aligned the peak in ALC might not occur at 1200 or be no peak at any position of the Drive control. So when you jumper and if you see no ALC at 14.175 then repeat jumper test at 3.750 and 7.150. If Coil Pack alignment is done properly should see ALC peak around 1200 on Drive control.

One other thing is are you 100% certain that you are really seeing 100mv rms 8.830 mhz carrier at Cathode of D5? Are you using a O-scope to measure this?

If you have a RF Sig gen could turn the CAR Level Pot full CCW and inject 8.830mhz test carrier at D5 cathode. Set Sig Gen level for 0dBm = 224mv rms = 633 P-P. If no ALC with test carrier applied then vary the RF sig gen frequency high and low of 8.830mhz as the filter Fc may have shifted.

I dont think it is a problem with the diodes or the biasing divider resistors. The dc return path for D5 cathode is choke L1. If it had a shorted turn or was shorted the Carrier from BM would be shunted to ground. The dc return for D6 cathode is R15. If it has drifted very high or is infinite then D6 wouldnt turn on.

Also, I dont know how you are measuring the Carrier level at anode of D5 when flipped to Send, but suggest you remove the test probe when peaking the Drive control to make sure it isnt dragging the level down.

Phil:

One other thought. You may want to examine D5 and D6 solder pads to see if any work done there. Someone may have changed out the diodes and no way to know what was installed.

Per the Toshiba datasheet curves the 1S1587 has a low forward bias voltage requirement for decent forward current values. For example 0.40vdc results in approx 1.0 ma forward current.

A 1N4148 switching diode at the same 0.40vdc results in forward current of approx only 10 ua.

Who knows with an NTE or other sub.

This is why I previously stated it would be good to see 0.5 to 0.6 vdc forward bias.

I have just purchased this TS830S for 50 GBP - around 62 US dollars at the current rate of exchange (a bargain wherever you look at it from). The previous owner said that it had suffered 'flashover' in the PA and that the main fuse (240VAC, 3A) had blown. You will see from my QRZ.com entry that solid state is a bit of an unknown country to me but I can fix valve (tube) stuff with my eyes shut. I am going to take this one very slowly so that I do not damage the silicon end of this rig.

Evidence so far:
6146Bs visually OK with no inter-electrode shorts (I have new spare 6146Ws available). PA compartment clean with no burns or smells (the whole rig is clean and tidy). PA plate blocking capacitor OK. 6146 cathode resistors (4 x 20 ohms in parallel) appear 'as new' and not scorched.
Cathode to ground reads 7 ohms but I think there's a couple of ohms getting lost in the test leads to the non-fancy DVM. Antenna relay contacts on the transmit side of RL1 are scorched and pitted.Does this collection of evidence point to a clear fault or should I keep looking (where?). If the problem is the antenna relay going intermittent and removing the load from the PA (result = sky-high plate current + arcing at the relay?) then can I swap the connections on the relay (RL1) from one side to the other? The antenna changeover is RL1-1 and RL1-2 connects to the 'remote' socket that I shall not be using.

There's a huge fund of hybrid know-how out there - any thoughts on this one?

Best wishes - Peter G3PIJ

Hi Terry,

> One other thing is are you 100% certain that you are really seeing 100mv rms 8.830 mhz carrier at Cathode of D5? Are you using a O-scope to measure this?

I am quite sure but I will re-check. I'm using a high bandwidth (> 100 MHz) Tektronix oscilloscope for both the DC and AC measurements. A 10X probe is used with a 1 megohm input resistance on the scope. I've verified the DC levels are correctly measured with my scope settings and probe using a bench DC power supply set to a known voltage, as well as using the scope's provided 5V amplitude square wave terminal. To be sure, I'll use a RF signal generator and set it to a known amplitude and re-verify my measurement set up before going back to D5 cathode.

> Also, I dont know how you are measuring the Carrier level at anode of D5 when flipped to Send, but suggest you remove the test probe when peaking the Drive control to make sure it isnt dragging the level down.

In SEND mode on TUNE or CW, I measured the RF carrier level at the D5 cathode (where I saw the carrier) by getting on the solder pad on the foil side of the board. After that, I repeated the process for the carrier level at D5 anode (where I did not see the carrier). Finally, I removed the probe for my attempts to get an ALC response in TUNE or CW mode so I wasn't loading it there.

I'll try to get on the diode leads themselves and repeat the measurements.

> You may want to examine D5 and D6 solder pads to see if any work done there. Someone may have changed out the diodes and no way to know what was installed.

I noticed before beginning my investigations that the D5 cathode solder pads on the foil side of the board had some scratches so it certainly is possible that someone has changed out the diode and that as you mentioned, the forward drop of 0.3 to 0.4V is not sufficient to turn the diode on hard.

On my next test session which could take a couple days or so, I'll try the RF carrier injection and the multi-band jumper tests and report back.

Peter,
I have 3 DVMs and they all have between .2 to .5 ohms meter lead resistance when the leads are shorted with the meter resistance set to 200.
I have a video on my website that shows how to calculate the final tube cathode voltage with 60ma idling current flowing in the final tubes then how to calculate the voltage drop across the meter.

http://w5rkl.com/wp-content/uploads/2015/02/TS530-TS830-Cathide-IP-meter-circuit.wmv

As the end of the video states, you can change the value of the cathode resistance to another value, such as 7 ohms in your case, then use the same 60ma of idling current, you will see an increase in cathode voltage which will result in an increase in voltage drop across the IP meter resulting in erroneous IP meter indications.

I recommend you replace both 6146Bs with NOS known good 6146B tubes. I also recommend you replace all 4 final tube cathode resistors with new 20 ohm 1/2 watt resistors.

Peter,

There several replacements for RL-1 that use two cheap plug in relays. You remove your relay and solder in a circuit board that has the relays. Do a google search and you will find tee choices. Good luck.

Hi Terry,

I managed to clear a few minutes and so I returned to the subject today, ultimately with success. I jumpered D5 cathode to D6 cathode using a 0.1 uF capacitor as you suggested. The radio's TX section came to life - ALC worked as intended and I was able to get between 80 and 100 watts out on all bands in TUNE and CW using the K4EAA tuning procedure, which in each case I was able to peak to ~225 mA plate current near max power output. DRIVE was almost right at 1200 position for most of the bands although it was a little to the right for the 28 MHz and higher bands. A Diamond wattmeter and a dummy load were used in the tuning process.

So all downstream is working fine. I guess I'm now suspecting that D5 is an incorrect diode as you mentioned and may not let much of anything through. I could try to get a 1S1587 from Walter as earlier suggested and put it in at D5. Or I could try and increase the forward bias on the diode there to 0.6 V, I presume by changing out one of the biasing resistors. What would you do?

Well these old phenolic boards dont like to see very many unsolder and resolder evolutions. Even a chance of lifting a foil if you have good vacuum de-soldering station or Hakko gun. Also, the molex connectors on the IF board can be problematic and you would be advised to do a good visual on all the pin soldering.

So since you need to pull the board to replace D5/D6 I would probably measure all the bias resistors and replace any that are outside of tolerance. I think most if not all are 5%.

Other option would be to contact Walter Dilley and see if he has a good pulled IF board and swap boards. If you do that see if he has a Rev 53 board. If not, a Rev 33 will be fine.

Mike -

By checking against low-value high-stability resistors, it seems that my analogue AVO meter is the most accurate in the 0-10 ohm range. The cathode-ground resistance of the PA is 6.5 ohms which, as you say, will make the PA current meter read incorrectly. The four 20-ohm resistors currently fitted are carbon composition so it seems they have drifted high, as is usual with this sort. My stores do not contain any 20-ohm resistors but plenty of 18 and 22-ohm preferred values. Testing two 18-ohm and two 22-ohm all twisted together in parallel gives me dead on 5 ohms. Can I get away with wiring 2 x 18 and 2 x 22 into the 6146 cathode circuit?

Next question (Hugh) - the antenna relay contacts are scorched and pitted on the TX side. Whether I rewire to the 'fresh' side of the relay or replace it, all I'm doing is fixing the symptom. The question remains - what is the underlying disease?

Many thanks for your comments so far.

Topic: 55709 Message: 55709

I have a TS-820 that I want to hook up to my Heathkit SB-200. I'm clear on the keying interface, but I had a couple of questions about the ALC.

1. Do I need to use the ALC? I think the answer is yes.

2. If I read the documentation correctly, the 820 has a -6V ALC threshold voltage and the SB-200 is -10V. I assume I need to drop the voltage, is that correct? What would be the best way, a zener?

Hi Gary,

I am a little new to this users group, but feel I can make comment on your question.

I am using a Kenwood TS520SE along with a Heathkit SB230 that I converted to use a single GI7b Russian triode.

The drive requirement for my SB230 is somewhat similar to your SB200.

I have not had much luck using ALC lines between different makes of equipment, but an inline 10k pot could make your two pieces work with each other, and is worth the try.

Rather than use an ALC line I have elected to do the following-

The output for my TS520se is a little too high for my SB230, if the 520 is loaded up correctly for 200 watts input, so I load the TS520 up for the 160 watts input cw level and see about 100 watts output PEP, in sideband mode.

This 100 watts PEP output is just perfect to drive my SB230.

Hope this is helpful to you.

OK - no kludge! I've found 20-ohm resistor packs on Ebay UK for the equivalent of a dollar and a half - for ten (!) - but no import delay. I shall replace all the other resistors associated with the PA before slowly winding up on a Variac with voltmeters hanging on the HT rails. I am assuming that my NOS 6164Ws date stamped 1982 will be OK substitutes for the original 6146Bs - I shall neutralise them later if nothing catches fire in the meantime.

Thanks also for confirming my suspicion that the burned relay contacts are most likely due to high SWR switching at some time in the past. I'm wondering if it's possible that the input capacitor of an ATU can kick back a charge into the TX on changeover - especially a T-match that can have a multitude of settings for 1:1 but only one position of the controls for a high-efficiency match.

55713. No ALC on TS-530S

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-10-29 23:44:31 UTC
From: louiswilen@...
Topic: 55713 Message: 55713

My TS-530S, which I have owned since new, is suddenly experiencing No ALC on all bands.

Background: Rig operated perfectly over the years. Although it is 34 years old, it has only about 11 years of (very careful) use, as I was not very active during about 23 years of ownership. Therefore, I have not replaced any components over the years except for the driver tube and the bandswitch coupler. I carefully replaced the bandswitch coupler about three weeks ago only because it was starting to develop a tiny crack. The bandswitch worked fine for at least 3 hours of QSO's after I replaced the coupler and it continues to work fine. The rig continued to operate fine after replacement of the bandswitch. I rechecked the coupling today and it is installed correctly. Therefore, I doubt that replacement of the bandswitch caused the problem, but I wanted to mention this just in case.

I pay close attention to meter readings, etc. and there was no indication of weak tubes or other problems before the failure. I realigned the rig about two years ago, and it actually needed just slight adjustment of a few pots. I have reasonably modern test equipment with NIST traceable calibration so I can measure and inject signals as required. I also have the KW service manual and lot of other docs that I've read. (However, that does not mean that I am an expert troubleshooter on this rig, as my electronics knowledge is more in the digital area and in software development.)

Receive continues to be excellent on all bands even with the No ALC failure.

Yesterday, shortly after powering up the rig just to listen, I noticed a faint burning odor near the rig for about a minute, but no smoke. I'm not even sure that the odor came from the rig but in hindsight, the odor probably did come from the rig. Only when starting to tune up the rig today did I notice the No ALC problem.

I tried replacing the driver tube with a known good tube but that did not make any difference.

Careful inspection of all components reveals no visibly burnt components.

Following Terry's "Driver Stage Testing" doc, I made the following observations:

With SG off, Drive at 12:00, VFO at 14.250, CAR level full CW, I used a 10 meg ohm probe at pin 5 of the final tubes to measure RF voltage with the rig in Send mode. Peaking the Drive control, the highest voltage that I got was 4.4v P-P. The 20 Mhz low pass filter in my Tek 2445 is "on". I note from TErry's document that I should see about 127v P-P.

Next I measured voltage at TP-4 on the RF board. With Drive fully CCW, I got 3.25v P-P. At 12:00 it was 5.10v P-P. Fully CW it was 9.45v P-P.

What should I check next?

Thanks very much.

Louis,

Firstly are you saying absolutely no alc?

Before looking for other issues, look a the basics first.

With the radio open, carefully tap the relay on the IF board using s plastic or non conductive tool.

A lot of the problems come from this relay.

Your driver tube could also bring the culprit.

Check r15 & r16 56k on rectifier board. Ensure you have disconnected from mains power and allow the hv to discharge completed, no ifs or buts.

Check the 20 ohm resistors on the final board, they are carbon composition and do fail without obvious signs.

No ALC at all.

I have tried another driver tube that is known to be good.

I didn't lift the 20 ohm resistors on the final board, but since they
are in parallel they should read 5 ohms altogether. They read 5.2 ohms
with my Fluke 179 (very accurate meter), which is within acceptable limits.

I will do the other checks that you suggest and will post the results.
I understand the HV precautions and know how to discharge properly, but
thank you for the reminder.

Louis:

If you are able to set the resting plate current to 60ma then you have approx -55vdc to -60vdc operating bias. This means you have filaments lit on the finals and have cathode emission. Now you need RF drive level on positive going peak of the waveform to overcome that dc offset and make control grids positive with respect to the cathode for grid current to flow.

If I understand your post you are varying the the Drive control full range from full CCW to full CW. You get max RF drive at the control grids of the Final tubes of approx 10v P-P with Drive Control full CW. Should get max closer to 1200 if Coil pack is aligned properly and your probe capacitance is not influencing the circuit.

Of course with -60vdc dc bias offset and only 5 volts peak rf drive the control grids are not positive with respect to the cathodes and there will be Zero ua grid current and therefore no ALC indication. Seeing the max RF drive with the Drive control at full CW position is usually indicative of probe detuning the Driver plate LC circuit or the LC circuit not being present due to bad band switch contacts.

I would repeat the TX Level Diagrams on 40 meters at 7.150mhz with Drive control at 1200 and run CAR Level pot full CW. Should see peak in RF drive closer to 1200 position.

I understand you tried another Driver tube. I would also measure the Driver tube anode and Screen grid voltages and control grid operating bias in TX mode. If no Pomona extension adapter then just remove the tube and measure at the tube socket pins when flipped to Send. I suspect you are seeing approx 0.4vdc operating bias, but SG voltage may be a problem based on the burning smell you noticed. May have a problem with R37/R36 divider resistors.

Lastly, it appears you have rf drive at TP-4. If it is excessively high can mean that the Drain of the Mosfet Mixers is not seeing the bandswitched in Mixer LC circuits.

Unusual for all of the bandswitch contacts to be bad, so repeat TX Level Diagram on 7.150 and 3.750mhz for starters.

Louis:

I forgot to mention to try gently wiggling and pressing on the Driver tube when flipped to Send. Sometimes can have bad tube socket solder connections.

Your TX level diagram readings indicate problem is in the Driver tube stage.

First thing to do is remove measurement error. You do that by repeating readings at 7.150 and 3.750 where capacitance of your scope probe will have less influence on the Mixer and Drive tuned circuits that are being bandswitched in at the TX Mixer Drain/Driver tube control grid and at the Driver tube plate/Final tube control grids.

If get same results then measure DC voltages at Driver tube socket.

As previously mentioned unusual to have all the bandswitch contacts bad. Ask self what is common?
1. Bad driver tube
2. Improper driver tube dc voltages especially operating bias or SG voltage
3. Bad solder connection at driver tube socket

If RF drive is low just on higher bands then Driver tube plate choke L39 may be the culprit.

Thank you for the help so very. Very much appreciated.

Here's an intermediate update:

Measuring using high quality 10:1 probe at pin 5 of a 6146B, SG=off,
CAR= full CW, Key=closed:

At Freq=7.150, the P-P at Drive=12:00 is 5.06v.

(The absolute peak in the 40M band was found with Drive=1:00, where the
P-P is 5.25v.)

At Freq=3.750, the P-P at Drive = 12:00 is 3.72v. This combination is
also gives the max P-P voltage for the entire 80M band.

Also tried jiggling and tapping driver tube, but that had no effect.
Also cleaned driver tube pins with Deoxit (out of the rig). By the way,
rig is very clean. I don't smoke or anything like that.

I will continue with the other items that you told me to check. In the
meantime, I am checking email if anything else comes to mind.

What RF drive level do you have at TP-4 at 3.750 and 7.150 with same CAR level and Drive control peak?

Next I would pull the Driver tube and measure DC voltages at Driver tube socket. Special attention regards operating bias on Control grid Pin 2 and Screen grid Pin 8.

If you leave the tube in and try to measure Anode with RF drive present (even at this low level) suggest you insert small RF choke in series with your Fluke 179 dmm red lead. Value not too critical.

For grins measure operating bias on Finals control grids. Since cathode resistors are good and you have adjusted bias voltage pot for 60ma zero signal plate current should see approx -60vdc.

60/1.414= 42.4 rms rf volts, So you will need greater than 42 rms rf volts or 118 P-P rf volts to have any ALC indication whatsoever. You report far less than this at Control grids of the Finals, thus no ALC indication.

It would be very rare to have an open C1 100pf coupling cap on the final board or an open C29 .01 dc block on the RF board.

To be on safe side suggest you measure RF drive voltage at the "S" solder lug on VC-3 drive air variable cap (small set of plates on cap nearest the PA cage that has the white neutralising lead wire soldered to the frame). Also measure at the Blue DRV lead wire at the wire wrap terminal post on the Final board.

You should have approx 60rms rf volts at "S" and approx 50rms rf volts at DRV. You can work the P-P. I provide rms as I use Boonton RF millivolt meter more commonly than O-scope.

/What RF drive level do you have at TP-4 at 3.750 and 7.150 with same CAR level and Drive control peak? /

At 3.750, I get 15v p-p at 12:00 drive. Also at 3.750, I found the max p-p at TP-4 to be 20v at 1:00 drive.

At 7.150, I get 14 p-p at 1:00 drive. Also at 7.150, I found the max p-p at TP-4 to be 20v at 3:00 drive.

I had the same experience. No one heard at sign on time (control or responding) after listening to the Swan Tech Net, then heard a couple of folks in a friendly QSO wondering where the net was. Same experience last week. Hope all is well and it's just band issues.

Was on frequency today at net time, but found no net control station heard today.

Had a nice chat with several Kenwood Hybrid owners/users on frequency at net time-

Carl W8WZ, K4EXF Jim, Lewis W3VVV, and myself, Bruce N4JHY.

Will give a listen next Saturday, and hope that the missing net control station for today is not in any distress with his absence.

73, Bruce N4JHY

Apologies for this rather novice question, but I want to be safe
instead of sorry:

When measuring voltages in the driver tube socket, I assume that you
mean voltage at each socket hole with respect to chassis ground, right?

Same question when measuring operating bias on the Finals control grids
-- measure with respect to chassis ground, right?

I went ahead and measured all driver socket voltages with respect to ground. SG=ON. Heater=ON. Tube is NOT in socket.

(Am I supposed to measure the heater from 4 to 5, 4 to 6 and 5 to 6?)

Hopefully I read the pins in the right direction. If not it should be obvious. Please let me know.

1: 0v

2: +250.9v

3: Started at about -0.9 and gradually drifting lower to about -0.7 with rig power on or off. Not sure what's going here.

4: 0v

5: 0v

6: 0v

7 :0v

8: -48.24v

9: 0v

Also measure at the Blue DRV lead wire at the wire wrap terminal post on the Final board. /

At both points, I get 3.45v P-P, which is 1.22v RMS, obviously far lower than it should be. Of course, this is with CAR full CW, SG=ON, and key closed.

Correction on the driver tube socket voltages. I neglected to put the rig in "SEND" mode when measuring. Here they are again. First voltage is with SEND off, second is with SEND on. These are in CW mode, except for pin 8, where the voltages changed when I put the rig in Tune mode as noted below.

1: 0v, 0v

2: +250.9v, +243v

3: Started at about -0.9 and gradually drifting lower to about -0.7 with rig power on or off. Not sure what's going here. (same with send on).

4: 0v, 0v

5: 0v, 0v

6: 0v, 0v

7 :0v, 0v

8: -55v, -24v in CW mode. -48v, +0.382v in Tune mode.

9: 0v

Louis,
The 12BY7 tube data sheet will show what each pin is and the pdf file can be found and downloaded at:
https://www.google.com/url?sa=t&rct=j&q=&esrc=s&source=web&cd=1&ved=0ahUKEwi2oKWa7YLQAhVD5CYKHaOfB8AQFggeMAA&url=http%3A%2F%2Fwww.r-type.org%2Fpdfs%2F12by7a.pdf&usg=AFQjCNG8dPWjSa4KYqhFqWY5G_3pZpxJeg&cad=rja

Pin 1 is the "Cathode", the "common current return path".
Pin 2 is the "Grid". The approximate negative bias voltage in RX will be -50VDC, increasing to approximate +.4VDC in TX.
Pin 3 is the "Suppressor Grid" and it is connected directly to ground, hence DC voltage is 0VDC
Pin 4 is one side of the filament and is connected directly to ground, hence 0VAC.
Pin 5 is the other side of the filament and is connected directly to 12VAC source, 12.6 terminal on secondary winding on power transformer.

Pin 6 is the "filament center tap", not used.
Pin 7 is the "Plate" with approximate +365VDC in RX, decreasing to approximate +320VDC
Pin 8 is the "Screen" with approximate +258VDC in RX, decreasing to approximate +230VDC in TX.
Pin 9 is the the other side of the 'Suppressor Grid", connected to ground, not used (connected to ground through pin 3).
Now the DC voltages stated above will no changed between TX and RX with the exception of the grid voltage on pin 2, with the tube removed. Measuring the DC voltages on the appropriate pins with the tube removed only indicates those DC voltages are present or not present, nothing more.

The reason there is 0VDC on pin 1, the cathode, is because there is no current flowing in the cathode circuit. Removing the tube there will be zero cathode current flowing in and there will be zero volts found on pin 1.

The driver stage operates in Class A which means current flows in the tube all the time, when biased ON, whether a signal is present at the grid, pin 2, or no signal is present at pin 2.
The Grid, pin 2, bias voltage will change between TX and RX whether the tube is in its socket or not.

The driver tube DC voltage and AC filament voltages are shown on the TS-530 service manual RF Unit schematic.

The driver tube pin 7 is hard to read. Pin 7 DC voltages are approximate +258VDC in RX and approximate +230VDC in TX. The differences in pin 7 voltages is based on the tube biased ON in TX and OFF in RX.

Notice pin 1 voltage in the above schematic is "0VDC" in RX increasing to +3VDC in TX. That change in cathode voltage can ONLY occur with the tube in its socket. Removing the tube from its socket you will not see those 2 voltages.

Next I would pull the Driver tube and measure DC voltages at Driver tube socket. Special attention regards operating bias on Control grid Pin 2 and Screen grid Pin 8.
If you leave the tube in and try to measure Anode with RF drive present (even at this low level) suggest you insert small RF choke in series with your Fluke 179 dmm red lead. Value not too critical.
For grins measure operating bias on Finals control grids. Since cathode resistors are good and you have adjusted bias voltage pot for 60ma zero signal plate current should see approx -60vdc.
60/1.414= 42.4 rms rf volts, So you will need greater than 42 rms rf volts or 118 P-P rf volts to have any ALC indication whatsoever. You report far less than this at Control grids of the Finals, thus no ALC indication.
It would be very rare to have an open C1 100pf coupling cap on the final board or an open C29 .01 dc block on the RF board.
To be on safe side suggest you measure RF drive voltage at the "S" solder lug on VC-3 drive air variable cap (small set of plates on cap nearest the PA cage that has the white

neutralising lead wire soldered to the frame). Also measure at the Blue DRV lead wire at the wire wrap terminal post on the Final board.
You should have approx 60rms rf volts at "S" and approx 50rms rf volts at DRV. You can work the P-P. I provide rms as I use Boonton RF millivolt meter more commonly than O-scope.

You measured wrong direction.

Also, wanted you to measure same conditions as you do for RF voltages only difference is with the Driver tube removed when flipped to Send.

Leave the SG switch off as it doesnt control Driver tube SG voltage. You dont want anything from the Final tubes other than transition from cutoff bias to operating bias and heater on for cathode emission. Leaving SG switch off is the way to test the Driver stage and ALC indication with no stress on the Finals.

So as to tube socket pin numbering convention you report -48vdc on Pin 8. That is Pin 2 Control grid and is the correct cut off bias voltage in Rx mode. Need to confirm it is approx 0.4vdc positive operating bias in Send. Need that to turn the tube on in Class A config. No 0.40vdc positive bias means no RF output at Plate.

It appears that you have Screen grid voltage, but no Anode voltage on Pin 7. It should be over 300vdc (approx 340vdc). It is not a good thing to have SG voltage applied and no Anode voltage. The screen will act like anode and draw high dc current and can exceed the dissipation rating of the small gauge SG wires and melt them. May have damaged tube already?

I would pull the Driver tube and leave it out until you confirm that you have in fact lost your anode voltage. Measure at Conn 7 Pin 4 (300A) to see if it is present at the RF board. If it is there then you may have lost plate choke L36. It is small green bodied choke. Often when it fails can see a dark brown band on it.

If not present at Conn 7 go to HV rect board and confirm there at 300B. If there then go to IF board and confirm there at Conn 4. If not there discharge 300 and 210 caps and then measure 470 ohm pi-filter resistor on IF board. Can go high or go open. A little high is no problem. If not at 300B on Rect board measure 470 ohm pi-filter resistor. Like the one on the IF board it can also go open.

Thanks Mike. It appears that I numbered the pins in reverse. The diagram shows the numbering going clockwise, so I guess that's the view as if I were holding the tube with my face pointed at the bottom of the tube. So when looking at the tube *socket* from the top (where the tube plugs in), the pins would appear to be numbered counter clockwise, right?

I think you may have disturbed some old corrosion so you may want to start by cleaning all one plugs. I use DeoxIT D100L that comes with a needle applicator. Put a small amount in each female end then plug in several times. No need to remove the excess DeoxIT because you use very little.

My TS-830S gave me a fit after I did some repairs till I cleaned the plugs.

>
> My TS-530S, which I have owned since new, is suddenly experiencing No ALC on all bands.
>
> Background: Rig operated perfectly over the years. Although it is 34 years old, it has only about 11 years of (very careful) use, as I was not very active during about 23 years of ownership. Therefore, I have not replaced any components over the years except for the driver tube and the bandswitch coupler. I carefully replaced the bandswitch coupler about three weeks ago only because it was starting to develop a tiny crack. The bandswitch worked fine for at least 3 hours of QSO's after I replaced the coupler and it continues to work fine. The rig continued to operate fine after replacement of the bandswitch. I rechecked the coupling today and it is installed correctly. Therefore, I doubt that replacement of the bandswitch caused the problem, but I wanted to mention this just in case.
>
> I pay close attention to meter readings, etc. and there was no indication of weak tubes or other problems before the failure. I realigned the rig about two years ago, and it actually needed just slight adjustment of a few pots. I have reasonably modern test equipment with NIST traceable calibration so I can measure and inject signals as required. I also have the KW service manual and lot of other docs that I've read. (However, that does not mean that I am an expert troubleshooter on this rig, as my electronics knowledge is more in the digital area and in software development.)
>
> Receive continues to be excellent on all bands even with the No ALC failure.
>
> Yesterday, shortly after powering up the rig just to listen, I noticed a faint burning odor near the rig for about a minute, but no smoke. I'm not even sure that the odor came from the rig but in hindsight, the odor probably did come from the rig. Only when starting to tune up the rig today did I notice the No ALC problem.

Thank you for clarifying the pin numbering. Working on next steps as recommended. Thanks so much for your patience.

In the meantime, here are the driver socket voltages with SEND=ON, CW mode, SG=OFF. This is using the right pin numbers.

1: 0

2: -24.8 (-48 in Tune)

3: 0

4: 0

5: 0

6: 0

7: 0.8, drifts lower as I watch.

8: +252

9: 0

Driver tube is currently removed. (I have several spares.) SG=OFF.

Okay, here's what I found.

Anode voltage on Pin 7 of driver socket is 341 vdc.

RF board Connector 7 Pin 4 is (300A) is about -0.50 vdc, drifts lower (toward zero) while measuring.

HV Rect board 300B = 341vdc.

IF board Connector 4 = -0.374vdc.

Not sure what you mean by "300 and 210 caps", but I discharged every large or nearby cap.
Measured 470 ohm pi-filter resistor but did not lift a lead for now. It measures about 700 K ohms, increasing over about 5 seconds to over 1 M ohm, I guess because my meter is charging the caps and giving a false resistance. But initial resistance within 1 second of measurement is about 700 K ohms, so I guess it's bad. Should I lift a lead next to check?

If any of this doesn't make sense, let me know and I'll re-measure.
Thank you for your continuing help.

Louis W3VVV

I don't knw what's going on, but I measured Pin 7 again (anode) and now
it's -0.4 vdc. Maybe I mismeasured at one point.

Also, to answer earlier question:

/So as to tube socket pin numbering convention you report -48vdc on Pin 8. That is Pin 2 Control grid and is the correct cut off bias voltage in Rx mode. Need to confirm it is approx 0.4vdc positive operating bias in Send.
/

Yes, (real) driver tube Pin 2 goes to 0.4 vdc in Send. So it's looking like the pi-filter resistor is bad. Anything else that I should do to confirm?

While monitoring the Plate voltage at the Driver tube socket do the following: 1. Wiggle Molex Connectors 3 and 4.
2. With an insulated tool wiggle 470 ohm resistor.

It appears that you have a high resistance connections/contact.

You should be able to read directly across R111 470 ohm resistor at its leads on the component side of the PC board.

Read DC volts from each of its two lead wires to chassis ground before measuring ohms. Should read zero volts.

I meant Conn 3 and Conn 4 on the IF board at either side of the 4 filter caps (300/210 supply caps).

If you find the intermittent and high resistance contact is at either molex connector you will have to remove the IF board. I can provide some direction on how to remove the molex connectors that minimizes pulling 4 or 5 off the board. Hate to see a grown man with tears in his eyes!

Wiggling had no effect.

I also pulled and cleaned the connectors with DeOxit. Don't worry, I'm very good with difficult connectors, almost as good a surgeon (which my brother is and I'm not but we both have the steadiness and good dexterity gene). But if you have tips for the future on Molex connectors, I'm always eager to hear them.

With rig powered off and caps discharged, DC volts from each of the resistor lead wires to chassis ground is 0.003 volts, which is effectively zero. Since the resistance is near 1 Meg Ohm, doesn't that pretty much prove that the resistor has failed?

Seems that the next step would be to obtain the right resistor and put it in parallel with the suspected bad resistor. Since the bad resistor is reading over 700 K ohms, it is effectively open. If that fixes the problem, it seems that the best fix is to clip the bad resistor right at the point where the leads enter it, then solder the new resistor to the leads left from the old resistor. That way I don't have to pull the IF board or risk lifting a solder trace. (However, I do have a PACE vacuum extraction rework station, just in case.)

What do you think?

P.S. Just to be clear, I cleaned only Conn 3 and Conn 4. I don't fix what's not potentially broken because I know doing so leads to other problems.

Yes can tack solder a parallel resistor with present high resistance one.

You can also just jumper it out temporarily with alligator or mini-grabber test lead. That will result in 5 to 10 more dc volts which is not a problem.

If that restores stable anode voltage and RF drive and ALC indication, you can cut leads long off the existing resistor and tack solder replacement 470 ohm on the stub leads.

I dont like to make component side repairs by tacking parts in place, but I see it done quite a lot and is a way to avoid board removal and potential molex connector problems. Very easy to induce a hair line crack at the pin pad to trace transition zone.

OK very important to not impart any side to side rocking motion when removing the plug from its body.

If must rock while applying upward force limit it to end to end.

Hair line cracks will be obscured by the solder mask and produce intermittents that can give you fits sometimes as latent failures.

On longer body connectors best to gently pull up at each end and then move needle nose to center of the body to complete the removal. Also use mini-needle nose that have serrated jaws and not smooth jaws. Try not to slip off the body as can damage top edge and/or lead wire conductor insulation.

I can't thank you enough for your help, Terry (and others who helped, too). You made this seem easy -- although I'd be completely lost without your guidance.

Also, looking at the failed resistor, it appears to be rather cooked in the middle. The bands on the similar 470 ohm metalized film resistor on the HV board (although 1 watt, not 2 watts) are bright and sharp, easily seen as yellow - violet - brown - gold. The middle bands on the failed resistor are muddy looking, as if the resistor is muddy yellow - gray - gray - gold. So I guess this is how metalized film resistors look when they fail.

Arrow electronics is even offering free fast shipping for even a 50 cent part this month, so I should have the replacement in my hands in a few days.

Thank you again so much. Hopefully this will solve it but I'll let you know the final outcome when I get the new resistor. (I'm not going to bother jumpering out the failed resistor, but thanks for that tip.)

73,

Louis W3VVV

Thank you. I'll hold on to this. I usually pull straight up just
enough with needle nose pliers to create a gap, less than 1/10 of a mm.
Then I put a very fine screwdriver blade under the gap and lift gently,
smoothly and slowly with the screwdriver blade. That seems to minimize
pulling force on the connector on the board, since I'm really hardly
pulling it at all.

55756. Hybrid Net Update (October 30, 2016)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-10-30 21:09:33 UTC
From: Mark Gilger
Topic: 55756 Message: 55756

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

There was no Saturday net due to the DX Contest.

The Sunday net was run by me, WB0IQK. There were
10 stations checking in fairly good band conditions.

We had the following number of radios checking in.

3 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830S + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals

plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 ☐ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins

November 2015, Saturday net total = 66, Sunday total = 46
December 2015, Saturday net total = 55, Sunday total = 73
January 2016, Saturday net total = 129, Sunday total = 81
February 2016, Saturday net total = 98, Sunday total = 72
March 2016, Saturday net total = 74, Sunday total = 35
April 2016, Saturday net total = 101, Sunday total = 57
May 2016, Saturday net total = 51, Sunday total = 32
June 2016, Saturday net total = 39, Sunday total = 46
July 2016, Saturday net total = 52, Sunday total = 54
August 2016, Saturday net total = 28, Sunday total = 35
September 2016, Saturday net total = 64, Sunday total = 33
October 2016, Saturday net total = 50, Sunday total = 64 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

You will notice the driver tube socket pins are equally spaced between each other except where at the large space between pins 1 and 9.
Viewing the tube socket from above, driver tube removed, the pins are oriented CCW, starting with pin 1 on the "right" side of the large space continuing around CCW to pin 9 on the "left" side of the large space. The opposite is true when viewing tube sockets from the "solder" pin side where the pins are oriented "CW" starting with pin 1 on the "left" side of the large space continuing CW around the socket to pin 9 on the "right" side of the large space.
Knowing this is important when measuring voltages. Also having the tube schematic diagram, showing what each pin is, helps to determine what pin is connected to it's internal element.
I have a couple of tube manuals on my website you can download.
http://w5rkl.com/wp-content/uploads/2014/04/RCA-Small-receiving-tubes-1975.pdf
Tube manuals contain an extensive amount of information about tubes.

Subject: Re: [TS-520_820_530_830] Re: No ALC on TS-530S

  Thanks Mike. It appears that I numbered the pins in reverse. The diagram shows the numbering going clockwise, so I guess that's the view as if I were holding the tube with my face pointed at the bottom of the tube. So when looking at the tube socket from the top (where the tube plugs in), the pins would appear to be numbered counter clockwise, right?

  Louis,
The 12BY7 tube data sheet will show what each pin is and the pdf file can be found and downloaded at:
https://www.google.com/url?sa=t&rct=j&q=&esrc=s&source=web&cd=1&ved=0ahUKEwi2oKWa7YLQAhVD5CYKHaOfB8AQFggeMAA&url=http%3A%2F%2Fwww.r-type.org%2Fpdfs%2F12by7a.pdf&usg=AFQjCNG8dPWjSa4KYqhFqWY5G_3pZpxJeg&cad=rja

Pin 1 is the "Cathode", the "common current return path".
Pin 2 is the "Grid". The approximate negative bias voltage in RX will be -50VDC, increasing to approximate +.4VDC in TX.
Pin 3 is the "Suppressor Grid" and it is connected directly to ground, hence DC voltage is 0VDC
Pin 4 is one side of the filament and is connected directly to ground, hence 0VAC.
Pin 5 is the other side of the filament and is connected directly to 12VAC source, 12.6 terminal on secondary winding on power transformer.

Pin 6 is the "filament center tap", not used.
Pin 7 is the "Plate" with approximate +365VDC in RX, decreasing to approximate +320VDC
Pin 8 is the "Screen" with approximate +258VDC in RX, decreasing to approximate +230VDC in TX.
Pin 9 is the the other side of the 'Suppressor Grid", connected to ground, not used (connected to ground through pin 3).
Now the DC voltages stated above will no changed between TX and RX with the exception of the grid voltage on pin 2, with the tube removed. Measuring the DC voltages on the appropriate pins with the tube removed only indicates those DC voltages are present or not present, nothing more.

The reason there is 0VDC on pin 1, the cathode, is because there is no current flowing in the cathode circuit. Removing the tube there will be zero cathode current flowing in and there will be zero volts found on pin 1.

The driver stage operates in Class A which means current flows in the tube all the time, when biased ON, whether a signal is present at the grid, pin 2, or no signal is present at pin 2.
The Grid, pin 2, bias voltage will change between TX and RX whether the tube is in its socket or not.

The driver tube DC voltage and AC filament voltages are shown on the TS-530 service manual RF Unit schematic.

The driver tube pin 7 is hard to read. Pin 7 DC voltages are approximate +258VDC in RX and approximate +230VDC in TX. The differences in pin 7 voltages is based on the tube biased ON in TX and OFF in RX.

Notice pin 1 voltage in the above schematic is "0VDC" in RX increasing to +3VDC in TX. That change in cathode voltage can ONLY occur with the tube in its socket. Removing the tube from its socket you will not see those 2 voltages.

Subject: Re: [TS-520_820_530_830] Re: No ALC on TS-530S

  I went ahead and measured all driver socket voltages with respect to ground. SG=ON. Heater=ON. Tube is NOT in socket.
(Am I supposed to measure the heater from 4 to 5, 4 to 6 and 5 to 6?) Hopefully I read the pins in the right direction. If not it should be obvious. Please let me know.
1: 0v 2: +250.9v 3: Started at about -0.9 and gradually drifting lower to about -0.7 with rig power on or off. Not sure what's going here.

Next I would pull the Driver tube and measure DC voltages at Driver tube socket. Special attention regards operating bias on Control grid Pin 2 and Screen grid Pin 8.
If you leave the tube in and try to measure Anode with RF drive present (even at this low level) suggest you insert small RF choke in series with your Fluke 179 dmm red lead. Value not too critical.
For grins measure operating bias on Finals control grids. Since cathode resistors are good and you have adjusted bias voltage pot for 60ma zero signal plate current should see approx -60vdc.
60/1.414= 42.4 rms rf volts, So you will need greater than 42 rms rf volts or 118 P-P rf volts to have any ALC indication whatsoever. You report far less than this at Control grids of the Finals, thus no ALC indication.
It would be very rare to have an open C1 100pf coupling cap on the final board or an open C29 .01 dc block on the RF board.
To be on safe side suggest you measure RF drive voltage at the "S" solder lug on VC-3 drive air variable cap (small set of plates on cap nearest the PA cage that has the white neutralising lead wire soldered to the frame). Also measure at the Blue DRV lead wire at the wire wrap terminal post on the Final board.
You should have approx 60rms rf volts at "S" and approx 50rms rf volts at DRV. You can work the P-P. I provide rms as I use Boonton RF millivolt meter more commonly than O-scope.

OK---Your choice, but I would have a test jumper across it and driver tube installed in about 2 seconds to see if I had my transmitter back.

Also, I would install my Fluke 179 on DC ma range in series with the test lead and measure the current draw. Should be around 25ma or 3/10 of a watt. It makes me a little nervous that resistor discolored and failed. Especially since you reported smelling something hot on the RF board.

Not always possible to determine root cause of part failure. Sometimes they just get tired and die due to old age,but since I do this for paying customers I owe them a questioning attitude.

I can't thank you enough for your help, Terry (and others who helped, too). You made this seem easy -- although I'd be completely lost without your guidance.

Also, looking at the failed resistor, it appears to be rather cooked in the middle. The bands on the similar 470 ohm metalized film resistor on the HV board (although 1 watt, not 2 watts) are bright and sharp, easily seen as yellow - violet - brown - gold. The middle bands on the failed resistor are muddy looking, as if the resistor is muddy yellow - gray - gray - gold. So I guess this is how metalized film resistors look when they fail.
Arrow electronics is even offering free fast shipping for even a 50 cent part this month, so I should have the replacement in my hands in a few days.

Thank you again so much. Hopefully this will solve it but I'll let you know the final outcome when I get the new resistor. (I'm not going to bother jumpering out the failed resistor, but thanks for that tip.)

Yes can tack solder a parallel resistor with present high resistance one.

You can also just jumper it out temporarily with alligator or mini-grabber test lead. That will result in 5 to 10 more dc volts which is not a problem.

If that restores stable anode voltage and RF drive and ALC indication, you can cut leads long off the existing resistor and tack solder replacement 470 ohm on the stub leads.

I dont like to make component side repairs by tacking parts in place, but I see it done quite a lot and is a way to avoid board removal and potential molex connector problems. Very easy to induce a hair line crack at the pin pad to trace transition zone.

As it turns out, I had a brand new 560 ohm, 5 watt resistor in my spares box. Too large to solder in place but fine for test purposes. I clipped it in place and the rig came to life, just like new. Good ALC on all bands.

I also just measured current as you suggested. It's steady at 26 ma.

Thank you again. 73 73 73,

Actually, the meter reads 1 ma when connected in series with the resistor even with the rig off, so I guess that's just some residual power or meter error, whatever. But it's 26 ma transmitting, so that's good.

Some other good news: A problem that I had been ignoring appears to have has gone away. For the last couple of years, the plate current would sort of jitter around a bit (on the front panel meter) for a few seconds sometimes when tuning up, especially when the rig was first turned on. I thought about posting the problem on the forum but figured that it was too vague to describe. That problem appears to be gone.

I now have good ALC on all bands, although on 10M I have to turn CAR to about 3:00 to get ALC. I know that this means that my driver tube might be starting to get weak. I haven't been on 10M for a while so I don't know whether it was like this before the failure or whether the failure weakened the driver tube. In any case, that's an easy enough problem to fix by getting a new tube (if 10M ever comes back to life).

Usually the ALC indication will slowly fall lower under key down on 10 meters as the cathode emission falls off. Could be that you need a good Coil Pack alignment. We all talk about short key down time with respect to Final tube life, but the real weak sister is the Driver tube since it is running near tube data sheet maximum allowable plate current any time in Send mode. That is why important to allow it to rest between bands when performing driver stage testing.

One other thing to consider now that you have transmitter working. I would take TX Level Diagram RF drive levels from TIF to Finals control grids and log for future use. Invaluable troubleshooting tool. I would do this using same O-scope and 10X probe.

Load to 100 watts output at 14.175 and turn off SG switch and record the 4 RF voltages. Load to 100 watts out at 3.750mhz and turn off SG switch and record RF voltages and load to 100 watts output at 7.150mhz and turn off SG switch and record RF voltages. Higher bands is not as useful due to the probe influence.

The levels in the Service manual were taken at 14.175mhz using RF VTVM and a probe that had less than 3pf shunt capacitance.

I have taken them on all the KW hybrids using a Boonton 92E RF millivolt meter, a Heath IM-18 VTVM and 309C and PK-3 rf probes, a Tek 475 O-scope and 10X probe, and a Rigol DS1102 O-scope and 10X probe. Get slightly different readings and different effects on the position of the Drive control and the amount of ALC meter deflection. Through experience you will recognize measuring instrument effect and when arent seeing Mixer or Drive LC circuits.

You can also record them from TIF back to the BM for a learning experience, but not used as often as TIF isnt bandswitch specific and low or missing TIF isnt as common a problem.

Thanks Terry. Will record the voltages as suggested. If you have a list of specific measurement points already in your notes that you could share, that would save me (and others) a lot of time.

I have voltages recorded from when I last did an alignment -- which as I mentioned previously, was sort of a minimal alignment because very few pots and trimmers needed to even be touched.

The driver tube has only about 4 years of active use on it. I think I'll swap out the tube before doing any alignment. Not sure if good receive indicates that transmit alignment is good, but I can safely say that my TS-530S sensitivity is as good at my new IC-7300 (although the IC-7300 does beat the TS-530S a bit when the preamp is switched on). I am able to instantly switch between rigs to compare signals.

55765. ts-830s no meter defection plate tuning

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-10-30 20:12:31 UTC
From: on6cn@...
Topic: 55765 Message: 55765

hi,
ts-830s no meter deflection plate tuning in ip mode
the deflection meter is very small, i can make a dip, when looking very sharp,
the ouput is 100w no problem there
all info welcome

Hi Lewis, Bruce N4JHY here. I have been reading through all your correspondence with the users group as to the no ALC problem with your TS530s.

If you remember, I spoke with you on 40 meters yesterday, and you had mentioned your problem.

I must say that Terry is real sharp with these hybrid Kenwoods, and a wonderful help to many of us. He helped me with a speech processor problem just several weeks ago.

You couldn't ask for a nicer more helpful ham, and most times his only reward is a thank you.

The group is very lucky to have him and his kind way.

I you would, please tell me the resistor number that turned out to be the culprit, so that I might look at a schematic to see how it fit into the circuit to cause your problem.

Thanks, and continued best luck with your 530.

73, Bruce N4JHY

55767. TS-520SE No transmit in CW

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-10-30 21:18:09 UTC
From: tghotdogz@...
Topic: 55767 Message: 55767

Hello to the Group,

It's been a while since my last post, but I am looking for suggestions with an issue with a TS-520SE I recently acquired. After sorting out numerous other problems, the radio now receives fine on all bands and transmits out a nominal 100 watts in LSB and USB modes as well.
The problem is no transmit output in CW or Tune modes. Receive works fine in CW mode, but is also dead in Tune mode, (S meter shows signals - just no audio).
Thanks to all for any help / ideas.

Regards
Tom

Topic: 55713 Message: 55769

The resistor is R111 on the IF board. It's between the four large electrolytic caps and the edge of the board. 470 ohms, metal film, 2 watts. Fairly large resistor, easy to access.

With the power off, It can be easily tested without lifting either lead. Ground each side of the resistor to the chassis (with the power off and the rig unplugged just to be extra safe) for about a minute to fully discharge the capacitors. Then disconnect the grounds. Then measure the resistor. Mine was reading over 700 K ohms, which is way too high for a 470 ohm resistor. My meter tended to charge the caps so after a few seconds the resistance showed as over 1 M ohm, but the important point is that the resistor was way over spec.

The resistor didn't look abnormal at first visual inspection. On first inspection of the components, I was looking for a crispy resistor or obviously burn-in-half resistor and didn't see any. However, after the problem was pinpointed, it was apparent that the color bands on R111 were faded and the middle of the resistor was darkened slightly. I guess this is how metal film resistors sometimes look when they fail.

There is a similar resistor on the HV board (470 ohms, metal film, 1 watt). When I compared R111 with the similar metal film resistor on the HV board, it was obvious that R111 did not look normal.

I agree that we are very fortunate to have Terry's help on this forum.

73,
Louis W3VVV

Tom,
Place Mode switch to CW, plug CW key into the rear CW socket, turn VOX "ON", and press CW key.
Did the 520SE switch to transmit and you hear the CW side tone in the speaker (volume control should be set to 9 o'clock)???

Louis:

The measurement points are shown on the TX Level Diagram in your Service Manual on Pg 45.

Have to study the schematic to figure out where those points are. For example you cant tell be looking at the Diagram that you can get on the "S" solder lug of VC-3 to measure DRV level.

Also, the 10mv TIF signal isnt labeled on the Diagram as being located at Conn 7 on the RF board or at Conn 6 on the IF board or at block Diode D13.

Also, no O-scope waveforms are supplied so looking at TIF for first time can be confusing. Using LP filter setting with 10mhz roll off allows cleaner more stable look.

So I would mark up your copy of the TX Level Diagram. Can go to Fed Ex and have them blow up Pg 45 of your Service Manual and make a couple of copies that you can annotate.

If you have a specific question about a particular test point and signal level I can help with that.

Terry (K9TW) has an excellent paper on his web site that discusses, among other things, failure of the 470 ohm pi-filter resistors. The link to the paper is on this page:

http://www.k9tw.com/faqs

under "Screen Grid "Stopper" Resistor Replacement <https://drive.google.com/file/d/0B5NBmwIA2pskaTBoYVVKZFZtTlk/view?usp=sharing>".

Section #3 (on page 5) discusses the 470 ohm resistors.

Of course, I didn't see this paper until this morning, after finding the failed resistor with Terry's help yesterday (and Mike's help with the tube pin numbering).

Terry says in his paper "Anytime you find either one of these 470 ohm resistors discolored or burned up or shifted in value the first thing you should check is the output capacitor to make sure it is not shorted or leaky."

So following that advice, I checked the four large 22 uF capacitors. None were shorted. They each measured above 22 uF, actually 28 uF to 34 uF. I also checked the ESR of each of the caps (with a "BlueESR meter"), and it was under 1 ohm, which is fine. As shown in the IF board view in the service manual, all of this checking can be done from the Molex connectors near the caps without removing the caps from the board.

Louis:

I am a big fan of the KW hybrid design, but from time to time I find areas that I think could be improved upon and I feel that way about the two 300 supply 22uf 350wvdc filter caps.

The Driver tube anode voltage in Rx mode can run from 335vdc to 355vdc. That doesnt leave much head room.

So I always recommend that customers replace these electrolytics with 22uf 450wvdc rated units under the preventive maintenance/life extension umbrella. Since you have to remove the IF board to replace them I replace the two 210 supply caps as well.

A Nichicon 105 deg C Type PS(M) is what I install.

Kevin,
I will try and do some further research on this, but I have not heard of any other group member having the same problem(s). Check any security/firewall software you might have to make sure the "certificates" for what ever site you are visiting are current/up to date.

Kevin,
It may just be as simple as making sure that your computer clock is set correctly as well as the date. To save time, you can "google" security certificate problem(s), as I do not know what platform you are using

Hi Joe,

Clock and date are correct. I did some research, but the answers were confusing. I didn't always have this problem. It started a couple weeks ago. It's only with Yahoo.

I'll try to get some more answers and I'll keep you posted.

Thanks for responding,

Kevin,

To resolve this problem, submit this link from your browser:

https://www.sslshopper.com/ssl-checker.html#hostname=groups.yahoo.com

You should get a list of verification statements, each with a green checkmark. Any problems will be described.

My best guess is that your ISP is using a proxy server that incorrectly modifies the hostname when it forwards requests to Yahoo.

Since this is not Kenwood issue or a forum issue, I'll be happy to help you offline at louiswilen@....

Hi Joe,

I found a fix:

target principle name error means the certificate was issued for different server names than you use for pop3/imap and smtp. You'll get it if you use mail.sbcglobal.com as the server name and redirect you to att (or yahoo) servers. Click view certificate then Install Certificate - choose current user, the click Browse and install it in the Trusted Publishers folder.

I did this and it worked. I posted her just in case someone else has the problem.

Have a good one,

Kevin - N2FLP

Hi Kevin,

I saw your post with the solution. Actually, what you are doing is a workaround, but that's fine.

If not sure why mail.yahoo.com is being translated to "mail.sbcglobal.com".

If this is happening on all the computers in your house, then your ISP has a problem. If this is happening with just one computer, then you probably have a erroneous host table entry on your computer, which was probably added by some program. Normally on a Windows PC or a Mac, the hosts table is not used. I'd need to know a lot more to pinpoint the problem, but at this point, it sure looks like a problem created by your ISP, so you might give them a call.

Louis

Tom,

Place Mode switch to CW, plug CW key into the rear CW socket, turn VOX "ON", and press CW key.

Did the 520SE switch to transmit and you hear the CW side tone in the speaker (volume control should be set to 9 o'clock)???

Subject: [TS-520_820_530_830] TS-520SE No transmit in CW

Hello to the Group,

It's been a while since my last post, but I am looking for suggestions with an issue with a TS-520SE I recently acquired. After sorting out numerous other problems, the radio now receives fine on all bands and transmits out a nominal 100 watts in LSB and USB modes as well.

The problem is no transmit output in CW or Tune modes. Receive works fine in CW mode, but is also dead in Tune mode, (S meter shows signals - just no audio).

Thanks to all for any help / ideas.

Regards

Tom

Greetings group,
A group member has been having problems. It takes a bit of time to read through all the posts and other things that involve the group. What has jumped out was the "sbcglobal"dot"com reference. Not too long ago...a warning was issued by the group administration regarding a now banned group member using an "sbcglobal"dot"com address. This person was data mining and/or spamming group members..and even though it's against group policy to use profanity.....this member was "shit canned."

I suggest ALL group members to check their spam/firewall settings and make sure that ALL of your "stuff" is up to date...and to NOT open ANY attachments. The group administration tries to keep all the group members safe by filtering potential members as much as possible. To make sure that group members know what happens: if someone wants to join our group, the group administration gets a message. That message is reviewed. If for some reason, the applicant fails to provide requested information...which is asked for on the website..I will query the person to "verify ur name, call and qth." I will send that request using the "owner" address, and my "yahoo" address. If their is no response using either address...the membership request is REJECTED. Some may not think so...but it takes a great deal of time to "take care of the group." Not to whine too much...but I have numerous "winter projects" waiting...I'm happy that the XYL understands.

 Members have complained that the rules/policies are too stringent, but all we desire is to promote this group...while keeping it safe for its members. If you have a problem with the way this group is run...contact me OFF line

Tom,

Based on your comments that TUNE/CW RX and TX do not work BUT both USB and LSB TX and RX both work, that could be caused by a failure of the 3395Khz CAR Unit crystal. The CW 3395Khz crystal functions in TUNE/CW TX and RX. If it fails then you will loose TUNE/CW RX and TX.

To check for the signal you will need a scope and frequency counter.

Connect the scope and frequency counter to the CAR Unit's "OUT" terminal. In RX place MODE switch to CW and the scope should show a nice 800mv to 1 volt RF sine wave on the scope and the frequency counter should display approximately 3394.3Khz. Switch to TX and the counter should change to approximately 3395.0Khz and the scope should display a nice 800mv to 1 volt output signal. If you do not see those signals in CW/TUNE RX and TX then switch to USB and LSB. In USB you should see 3396.5Khz and LSB 3393.5Khz on the counter and a nice 800mv to 1 volt sine wave on the scope.

If you do not see the 3394.3Khz or 3395.0Khz signal in TUNE/CW RX and TX but you do see 3396.5Khz in USB and 3393.5Khz in LSB then the X1 3395Khz crystal has failed.

You can check with Walter Dilley, walter dot dilley at gmail dot com, he may have a spare CAR Unit board.

Thanks Mike,

The reason I didn't look at the carrier oscillator was that the radio receives fine in CW, but not in Tune. But looking at the schematic I see there are separate lines for transmit and receive to switch on the CW oscillator.
I will check the oscillator output tonight with my scope and verify it is working in transmit as well as receive.

In RX place MODE switch to CW and the scope should show a nice 800mv to 1 volt RF sine wave on the scope and the frequency counter should display approximately 3394.3Khz. Switch to TX and the counter should change to approximately 3395.0Khz and the scope should display a nice 800mv to 1 volt output signal. If you do not see those signals in CW/TUNE RX and TX then switch to USB and LSB. In USB you should see 3396.5Khz and LSB 3393.5Khz on the counter and a nice 800mv to 1 volt sine wave on the scope.
>
> If you do not see the 3394.3Khz or 3395.0Khz signal in TUNE/CW RX and TX but you do see 3396.5Khz in USB and 3393.5Khz in LSB then the X1 3395Khz crystal has failed.

55797. File - Message on approved membership.txt

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-11-01 11:40:04 UTC
From: TS-520_820_530_830@yahoogroups.com
Topic: 54481 Message: 55797

Welcome to the Yahoo Kenwood TS-520_820_530_830 Amateur Radio Group. This group is comprised of members who's interest is in maintaining and operating the Kenwood TS-520, TS-820, TS-530, TS-830, TS-510, TS-511, T-599/R599 and R820 Hybrid transceivers, transmitter and receivers. In addition, the group supports discussions covering the associated Kenwood accessories such as the VFO-520, VFO-820, VFO-230, and VFO-240 remote VFOs, the Kenwood antenna tuners, and the various Kenwood desk and hand microphones.

This is a restricted group requiring membership approval prior to receiving and posting messages to the group. To join the group simply complete the Yahoo Kenwood TS-520_820_530_830 Group's application process by clicking on the “+ Join Group” icon on the group's homepage. Select the desired method of receiving messages by clicking the appropriate radio button, then provide a brief description about yourself to include: your first name, your Amateur Radio call sign, your interest in the Kenwood hybrid radio, and the model of Kenwood hybrid you own, operate, or in the process of purchasing in the text box provided. If you are not a licensed Amateur Radio operator, no problem, simply complete the application process and provide the same information less the Amateur Radio call sign. Once you have completed the text, click the Join Group icon. Your application will be reviewed and approved by a group co-owner or Moderator. If you leave the application text box blank, your application for membership will be rejected. Simply reapply and provide the information requested and resubmit your application for membership.

New members are placed on a "Moderate" status. This means that any message a new member posts to the group must be approved by a group co-owner or Moderator before it appears on the group server for all members to see. The length of time a new member remains in a "Moderate message status" is determined by the members ability to adhere to, and follow the group's policies. The faster the new member(s) can prove they are adhering to, and following the group's policies, the quicker the new member's status will be changed to “Allowed”.

The “Allowed” status means the member can submit/post their messages without group co-owner or Moderator's approval. A member who's message status is set to “Allowed” may have their message status changed to "Moderate" if it is deemed necessary by a group co-owner or Moderator for one of the following reasons:

1. Failure to follow the group's policies after being informed by a group co-owner or Moderator
2. Knowingly violate any of the group's policies
3. Any improper behavior by the member that is deemed inappropriate by a group co-owner or Moderator

The group is moderated by both group co-owners and group Moderators. While we would like to have a group co-owner and/or Moderator present 24/7, that is not possible, as group co-owners and Moderators have a life too. Therefore, there will be times when a group co-owner and/or a moderator will not be present. This will affect the time a moderated member's messages may take to get approved/rejected. This occurs most often during major holidays Also, the group's server is not maintained by the group co-owner(s) or Moderators.

Therefore, when Yahoo has problems affecting Yahoo Groups, ALL members will simply have to wait for Yahoo to fix the problem. Group co-owners and Moderators also do not have any control over how the group's server handles attachments to messages or how message search results are provided.

Page 1

As stated above, this group has a set of policies that all members must agree to and abide by. If any member, new or old, that feels they cannot accept the group's policies, that member is free to terminate their membership at any time without notifying the group co-owners and/or Moderators.

Group's Policies:

1. Profanity of any type, regardless of the word and/or phrase(s) used in a message, is not allowed. This includes the use of abbreviation to improper words, use of symbols to substitute for letters, etc. In short, the use of profanity is NOT ALLOWED, PERIOD!!! The quickest way to get banned from this group is to use profanity!!!

2. Disrespect/Flaming any member regardless of the reason, is not allowed.

3. Taking over a thread by a member that changes the threads original subject and content, is not allowed.

4. Messages that contain as part of the message text, discussions of a member's private life are not allowed. Responses to messages are to pertain to the original message subject.

5. Long discussions that are products of an original messages are not allowed. If there are 2 or 3 members who wish to discuss a subject in more detail and at great lengths should take their discussions off the group and continue their discussions using private email addresses.

6. MESSAGES THAT DO NOT CONTAIN ACCEPTABLE MESSAGE SIGNATURES, WILL BE SUMMARILY REJECTED! It takes less than 5 seconds to ensure your message contains an acceptable message signature. There is no excuse for not adding a message signature to your messages. Political or religious signatures/statements are not permitted.

The following are examples of the ONLY acceptable message signatures:

Licensed Amateur Radio members:

Example:
“73s
John WA1ABC”

Non-licensed members

Example:

73s
Mary

If a member does not wish to include their Amateur Radio call sign in their signature, then simply use their first/given/Christian name ONLY, same as non-licensed members.

Each message signature must be positioned at the bottom of the message text and separated by at least one line.

For example:

Hi John,

Yes capacitor C25 is the right cap you should be checking. For details, review the schematic.

73s
Bill

Screen names such as JLH524 or MWPO125 are not acceptable message signatures. Screen names are acceptable ONLY when used as part of the member's email address.

The member's email address is not an acceptable message signature, regardless whether the member's name appears in the email address or not.

A member's “initials” are not acceptable as a messages signature.

A member may add up to 2 additional lines to their message signature. The additional 2 lines may contain a link to the member's website and a link to the member's Amateur Radio club etc. The addition of 3 or more lines to the message signature, listing the many different clubs the member belongs to, the positions they hold within the respective club(s), their professional position within the company the member works for, and other information is considered excessive and not allowed. The following is an example of an acceptable message signature containing two additional line:

73
Mike-w5rkl
www.w5rkl.com
Yahoo Kenwood TS-520_820_530_830 Moderator (Mike-w5rkl is no longer a Moderator, but used as an example--tnx)

In the past there have been members who state our group policies are too strict. We maintain strict group policies for 2 simple reasons:

1. To maintain good order and discipline in the group.
2. Provide a friendly group where all members are treated equally and an environment free of improper behavior

73
Yahoo Kenwood TS-520_820_530_830 Hybrid Group Co-owners and Moderators.

55798. File - Rules, For Sale or Want to buy Posts

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-11-01 11:40:04 UTC
From: TS-520_820_530_830@yahoogroups.com
Topic: 54620 Message: 55798

Rules pertaining to Occasional For Sale and Want to Buy Posts.

Members of the TS-520_820_530_830 Yahoo Group who have been members for at least 30 days may place " for sale" posts no more frequently than two in any 30 day period." Want to buy" posts are permitted immediately upon membership and are limited to 2 in any 30 day period.

For sale posts are limited to the sale of TS-510, 515, 520, 820, 530, 830, and the 599 series twins, as well as Kenwood accessories intended for use with these radios.
Also, group members may post "service equipment" for sale. This may include, but are not limited to: vtvms, various signal generators, and other testing/service equipment. Posts must include: the make and model of the item for sale, as well as an accurate description of its condition, and the asking price.

When the item is sold, please make a short post to that effect.

Replies and discussions regarding these posts must be taken off of this group either by direct e-mail to the seller or as directed by the seller.

Buyers and sellers are on their own. The TS-520_820_530_830 Yahoo Group, its owners, co-owners, moderators, or members other than the seller, hold no responsibility for the accuracy of the posts or the credibility of the seller or buyer.

We do not expect that members of this group will misrepresent, or in any way cheat other members. At the co-owners(s)/moderators discretion, we may choose to ban any member from making further for sale posts, or ban the member from this group entirely if we believe their posts or transactions are not of the utmost integrity.

We ask that those who buy and sell equipment as a main business not post here. We will allow posts from members who occasionally restore and sell equipment/accessories as stated above.

We expect our members to use discretion. If excessive traffic develops as a direct result of these postings, they may have to be discontinued.

Walter Breining, N9WB
Joseph T Stiles, WB7UQU

55799. Re: [TS-520_820_530_830] TS-520SE No transmit in CW

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-11-01 13:42:51 UTC
From: Mike W5RKL
Topic: 55767 Message: 55799
Attachments: 1 described; binary payloads are missing from this source WARC

HI Tom,

The CAR Unit has 2 output frequencies in CW mode

CW RX the output is CWR at 3394.2Khz (TUNE/CW)
CW TX the output is CWT at 3395.0Khz (TUNE/CW)

The frequencies listed are approximate, may be slightly different based on the alignment performed on the 520.

TUNE mode TX uses the same CWT 3395.0Khz CAR Unit output frequency. You can monitor the CAR Unit "OUT" terminal with a frequency counter and a scope to see the frequencies change between CW RX and CW TX. The easiest point to connect the counter and scope is at the GENERATOR Unit's "GEN" terminal. That terminal has the short coax cable that connect the CAR Unit "OUT" terminal to the GENERATOR Unit's "CAR" terminal. I use a scope and counter to check the CAR Unit "OUT" frequencies and output level.

The CAR Unit's output signal level should be between 800mv and 1 volt after adjusting T1 for maximum CAR Unit output signal level. The CAR Unit boards I have worked on/tested have an RF signal output level of approximately 950mv peak in CWR and 1 volt peak in CWT, USB, and LSB as seen on the scope (1 volt per division input level setting).

If you see both frequencies at the GENERATOR Unit's "CAR" terminal then move the counter to the GENERATOR Unit's "GEN" terminal where you should see the CW TX 3395.0Khz signal with the TS-520 keyed in TUNE or CW mode. The front panel CAR control needs to be set to a level that will unbalance the GENERATOR Unit's Balance Modulator in CW TX. The front panel CAR control varies a small DC voltage that is applied to the "BM" terminal. This small DC voltage is used to "unbalance" the "Balance Modulator" so the CWT TUNE and CW TX signal flows through Q1 and appears at the GENERATOR Unit's "GEN" terminal where it continues on to the IF Unit's "GEN" terminal for further processing.

The schematic segment below shows the GENERATOR Unit's Q1 and Q2 that are used in all transmit modes. Notice the "CAR" terminal on the right. The signal path is shown as "dashed line". The CAR Unit TX CWT signal path flows through C49 to the base of Q2. Q2 is an Emitter follower so the output from Q2 is at it's Emitter. The signal continues on through D6 and D7 through C8 to the CAR Null pot VR1 (100 ohm).

Trace the CAR Unit CWT signal (TUNE/CW TX) from the CAR Unit to and through the GENERATOR Unit.

I still have several cans of cabinet paint in addition to front panel trim ring paint for any one needing to do some painting on their hybrid rigs. The price is the same @ $13 a can plus shipping via USPS Ground.

So what I ask is that anyone needing paint, email me @ wb0iqk@arrl.net with their request.

73'S,
Mark, WB0IQK

Topic: 55655 Message: 55802

Hi all,

Brief update: Walter Dilley sent me a free replacement set of switching diodes (no IF boards available at the moment) and I'll be pulling the IF board and installing those. I will also do the resistance checks Terry suggested. I need to replace the HV caps as a preventative measure anyhow so it all works out.

I'd like to again thank Walter and Terry for being an outstanding credit to the hobby and providing such excellent support on this ongoing topic - all extremely well done, and received with much gratitude.

More updates once the repairs are effected.

Phil W1PJE

55803. Re: TS-820: no drive and no output

Phil:

Now is time to do a very good visual on the molex connector pin pad soldering. Need good lite and magnification. I have spare molex plugs that I plug into the connector and gently rock as I watch the pins for any movement. Sometimes will see a circumferential hair line crack around the pin where the solder didnt wet very well to the pin. Do not try to reflow this solder. It wont work well and can use too much heat. Need to remove the old sublimated solder, sand or file the pin to brite metal, and re-solder. Must make sure the pin is fully seated against its shoulder. Again I do that by inserting a mating plug.

If you are going to do a lot of work suggest you contact Walter Dilley and see if he can harvest an assortment of molex plugs with some lead wire on them. Good for doing the solder work described above and for troubleshooting and bench testing boards.

When re-solder is complete I would then measure the resistance from the new soldered pin down the trace where you can get other DMM probe on. Should see approx 0.1 to 0.2 ohms. If can get on with mini-grabber use free hand to gently rock the connector and if the resistance changes value or goes open you have a hair line crack at the pin pad to trace transition zone and hard to see as it is obscured by the solder mask. If no mini-grabbers or spare plugs then get some help for this test.

Any place you see resistance go high or open you need to scrape off the mask with Xacto knife or other sharp tool down to brite copper and then either drag solder across the crack or install a short jumper from a 1/4 watt resistor tinned lead to bridge the crack. I hate to do this on any board and dont do it on my personal boards, but I give customers a choice. Board swap is more expensive, but get radio back as built.

Last thing to check especially on the long molex connectors on the IF board is make sure the connector body along entire length was fully inserted into the PC board and held firmly during solder. I have some pictures I could share where one end is inserted properly and other far end is barely inserted. Makes for some interesting intermittents and fun trouble shooting.

Terry K9TW

George,

The final amplifier neutralizing procedure is on page 26 paragraph 6.4
"TRANSMITTER NEUTRALIZATION"

An analog VTVM with RF probe can substitute for the RF volt meter. You
can find analog VTVMs on eBay rather cheap and you can build the RF
probe yourself. If you have access to a 30Mhz or higher scope then use
the scope in place of the RF Volt meter. Pay attention to the "CAUTION"
notice in the TS-530 User manual as shown above!!

The final amplifier neutralizing procedure is also in the TS-530S
service manual, page 40, step 19. I cut and pasted step 19 from the
TS-530 service manual page 40.

You should not attempt to service your TS-530S without the service
manual and appropriate test equipment.

If you do not have the TS-530S User and service manual, you can download
them from my website at the following links:

http://w5rkl.com/wp-content/uploads/2014/04/Kenwood-TS-530SP-manual.pdf

http://w5rkl.com/wp-content/uploads/2014/04/TS-530S_Service.pdf

You will need a non-conductive screw driver to adjust TC1 inside the
final amplifier enclosure. There is HV on that cap and using a metal
screw driver can cause a short damaging the 530.

If you do not have the experience working around High Voltage, +920VDC,
then I recommend you find a local ham who has the experience to help you
neutralize the final amplifier in your TS-530S. You could easily damage
the TS-530 and/or you can receive a severe shock if you are not careful.
There is no such thing as a slight "tingle" shock from "+920VDC"!!!! In
short there are voltages inside the TS-530 that can easily KILL YOU!!!

Mike,

Thanks for your information and detailed description of the signal path. I will get the radio back on the bench tonight and report back to you and the group what I find.

FYI – I did verify that the carrier control does apply a small DC voltage to the balanced modulator.

Regards

Tom

55813. Re: [TS-520_820_530_830] Neutralizing new finals

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-11-01 21:53:12 UTC
From: Rory
Topic: 55792 Message: 55813

I also found this in the files section:

There are two ways to neutralize a Kenwood TS-520, 820, 530, or 830.

First method: (requires an oscilloscope)
Connect the rig to a dummy load through a T connector.
Tune up your rig for full power in CW on the following frequency depending on your rig.

TS-520 28.5 MHz
TS-820 21.3 MHz
TS-530 28.5 MHz
TS-830 28.5 MHz

After tuning, place the SG switch to off.
Connect an oscilloscope by way of a X10 probe to the T connector.
Adjust the neutralization capacitor for lowest indication on the scope.

Second method:

Connect your rig through a wattmeter to a dummy load or an antenna that will produce a very low SWR at the frequency below.
Tune up the rig for full power on CW on the frequency below.

TS-520 28.5 MHZ
TS-820 21.3 MHz
TS-530 28.5 MHz
TS-830 28.5 MHz

Leave the SG switch ON.
Reduce the carrier control for around 50 watts. This is not critical. . Be sure that the drive is set for maximum on the ALC scale
Place the meter switch in the IP position.
While slighting moving the Tune control, the output on the wattmeter should peak at exactly the same point as the IP meter reaches the minimum of its dip.
Nudge the neutralization capacitor a bit at a time until this condition is achieved.

Notes:

If you are installing new tubes or if the neutralization is considerably out start with the capacitor at 50% meshed.
Probably working from here to the more open position will bring you to the proper point, but this is not always the case.

In CW, set the carrier control for about 50 watts out.
This watt level not critical.

When you get near the point where the dip and peak output coincide, check first the load and then the plate for maximum output with the carrier set for around 50 watts.
Then see how far from the dip you are. Nudge the capacitor and check again.

This condition will only occur on or near the frequencies specified above.

Use a plastic tool if possible because there is high voltage on the neutralization capacitor.

Even if a plastic tool is used, often it must be removed before neutralization is checked.

Final unit cover must be in place for proper neutralization.

If you have trouble turning the neutralization capacitor with the plastic tool, a metal screwdriver with a good plastic handle can be used as follows:

Place two layers of shrink tubing over the screwdriver shaft to avoid contact with the outer edge of the neutralization capacitor access hole. Remove the rig from transmit before inserting a screwdriver or a metal tipped tool.

Be sure the plastic handle of the screwdriver is sufficient to protect you from the high voltage. Do not use a wood handle screwdriver.

The screwdriver must be removed completely to check for a neutralized condition.

Another solution would be to rewind the choke yourself. Instructions for rewinding are at:

http://www.k9tw.com/faqs

What are the TS530/TS830 RF Plate Choke Specs?
<https://drive.google.com/file/d/0B5NBmwIA2pskTmxzMnhQN0d4dGs/edit?usp=sharing>

I have not done this myself for this particular choke but it appears to be very easy.

However, I'm not certain if the TS-520 plate is identical to the TS-530S/TS-830S choke. Maybe someone else here knows and could comment.

The TS520 Plate Choke is not the same as the TS-530.
The TS-520 is a multi ring wound choke as shown in the following TS-520S final amplifier picture.

The TS-530 final amp plate choke is a single layer wound choke as shown in the following TS-530S final amp picture

The 530/830 solenoid wound choke will work fine in the TS520 or TS820, but not the other way around.

The 530/830 choke was wound to ensure there are no series resonant holes near the WARC bands. There were no WARC band privledges when the TS520 and TS820 were in production.

The pi-section weave wound 520/820 choke has series resonant holes near the WARC bands and will burn up if run in a 530/830 rig. I have a couple of pictures my website that show a TS820 that was modified to cover the WARC bands and one that was installed in a TS830.

Hand winding a weave or honey comb choke is difficult. There are some manual coil winding machines designed for this and may find a YouTube video showing them in action.

That being said I prefer to go back with original components whenever possible and I would contact Walter Dilley and see if he has a TS520 or TS820 choke. Can also find them or a complete PA cage from time to time on Ebay.

"The 530/830 solenoid wound choke will work fine in the TS520 or TS820, but not the other way around. "

Thanks Terry! This is what I was looking for. I want to try winding one myself and the instructions provided on your Web page are fantastic. I do not have an LCR meter or other resonant circuit test equipment (other than a scope) but, I think I can get pretty good confidence that I did the job right by watching actual performance of the TS-520 at both low / high power and high / low frequencies. I can also make RF envelope measurements with the scope, which should help in evaluating the overall characteristics of the "modified" final stage.

I am so glad I joined this group! There is a wealth of information that could not be found anywhere else.

Thanks to everyone for your replies. I hope to be able to make some useful contributions to group as time goes on.

Thanks, Mike. I am going to try the "wind it yourself" option first and if I do not have success, I will try to contact Walter Dilley to see if he has one of the originals.

Best Regards,

John

Phil,
The MAJOR difference is the frequency spread used by the VFO.
The 520 series VFOs (both main and remote) us the same VFO with a frequency spread of 5.5MHz at "0" (zero) to 4.9MHz at "600"
The 820 series is the same VFO for both the main and remote but uses a frequency spread of 5.5MHz at "0" (zero) to 5.0MHz at "500"
The above info is stated in both service manuals

The other differences are arrangement of controls and cosmetic differences.

Mike and George:

Let me preface my remarks by stating the everyone on this forum is fortunate to have Mike and his willingness to make the time commitment that he makes and the repeated safety emphasis that he makes in his responses.

"You will need a non-conductive screw driver to adjust TC1 inside the final amplifier enclosure. There is HV on that cap and using a metal screw driver can cause a short damaging the 530"

However, in this case the warning about HV dc on the neutralizing capacitor rotor shaft with its screw driver slot is not accurate. There is no HV (900vdc) or any dc voltage on the NC cap either fixed plates or rotor. I suspect Mike didnt look at the schematic and has succumbed to the folklore that we all see about the danger of high voltage being present on the NC cap. We see that on this and many of the forums and I myself have been guilty of perpetuating the myth.

Had Mike looked at the schematic (of which he is an expert) he would have seen that the NC is tapped on immediately downstream of the Plate Block Cap and therefore no DC voltage is present. If there was 900vdc the safety choke would appropriately blow the fuse so that 900vdc would not be at the SO-239.

With 100 watts into a dummy load or antenna there will be approx 25 P-P RF volts or approx 8 volts rms on the NC cap rotor screw driver stub shaft. That out of phase 8 rf volts is brought out of the PA cage on a white lead wire to the frame of VC-3 air variable Drive capacitor where it makes its way to the control grids of the final tubes. They would never bring 900vdc out on that white lead to the RF board. If you could access the fixed plates of the NC cap there would be approx 1600 P-P RF volts or approx 560rms RF volts and you would not be happy contacting that. When you neutralize with the SG switch turned off there is only a very small RF voltage level at the fixed plates and rotor of the NC cap.

So, why the Caution in the TS530 Maintenance Section of the Owners Instruction Manual? My guess is that it is a carry over from the TS520 and/or TS820 manuals. Procedure writers seldom start with a blank sheet of paper. Almost always have a template and/or a previous rev that they cut and paste from. Also, it tells me that the draft procedure was not handed to an SME (subject matter expert) to dry run in the field or on the bench. Had that been done the SME (knowledgeable and experienced Kenwood service tech) would have told the writer that the caution was not applicable to the TS530 and TS830 rigs and that the writer had broken a cardinal rule by placing a caution after a step. A recipe for disaster.

The caution does clearly apply to the TS520/820, but not because there is high DC voltage on the NC cap. It is because they dont want you inside the PA cage. You have to insert a tool thru a small hole in the top of the PA cage to engage the NC cap rotor slot. That tool depending on the lead dress of the parasitic suppressor on the front Final tube may actually be in contact with the bare 900vdc lead or just millimeters away. If you look into that hole and can see the bare tinned lead extending into the tool shaft area I suggest you shut down and discharge HV caps and remove PA cage cover and remove the solder at the plate

choke on the parasitic suppressor lead and re-dress the red-brown phenolic plate cap so that the lead wire is not in the access hole window. Most of the time this solder is sublimated anyway and good to get rid of it. I find that I have to do this on about at least 50% of the 520/820 rigs I service.

On the TS530/830 rigs the NC cap is turned approx 90 degrees in the PA cage and the rotor stub shaft with screwdriver slot is on the bottom side of the radio underneath the Final board. There is a U shaped slot cut in the Final board so you can get your screwdriver on the NC cap. There is no reason to remove the PA cage cover on the TS530/830 rigs. As mentioned above there is no DC voltage present, but it it a good idea to use an insulated screw driver (mine has 3 layers of heat shrink on the shaft) so that you dont have to keep straight in your mind which rig you must use an insulated tool and on which ones you dont need it. Easy to get confused and make a mistake so just human factor it.

On the TS530/830 you do need to be aware that you will have the rig on its side and you will be within reaching distance of the HV filter caps and the HV rectifier board where there is 900vdc and/or 300vdc. You can use a piece of 8.5 x 11 thick cardboard or a sheet of lexan or plexiglas to make a barrier to prevent accidental contact.

If you own the TS530 or 830 I suggest you annotate the owners manual NC step caution to state that it is not applicable and that the NC cap is accessed on bottom side of the radio at the U slot in the Final board and to not enter the PA cage and to be aware of the presence of HV at the Filter caps and HV rectifier board.

Also, I recommend using an insulated screwdriver to make the initial gross adjustment as the NC cap is designed to turn hard so it doesnt shift off set point. Yes the metal screwdriver will influence your ability to get the null due to capacitance effect. After making initial null the cap may be a little free-er and can then use a red plastic flat blade tool like Ken K4EAA sells. Can also homebrew a tool by turning down an oak dowel rod and filing a flat tang on the end to engage the slot in the rotor.

In summary:
1. There is no dc voltage on the NC cap in any of the KW hybrids. This is probably one of those folklore things like SWR?
2. The caution in the TS530 and TS830 documentation is not applicable.
3. On the TS520 and TS820 if the front Final tube bare tinned parasitic suppressor lead enters the access hole window do not attempt neutralization until that configuration has been corrected.
4. If you are going to neutralize the TS520/TS820 with the PA cage cover off (I routinely have done it). Must be extremely careful that your tool is very well insulated due to the very close proximity of 900 vdc at the front tube parasitic suppressor lead. It helps also if you select one that the flat blade fits snuggly in the slot. Must also be mindful that if your tool slips out of the screw driver slot on the rotor your hand could go forward and fingers could contact the 900vdc lead. Best to take the time to unsolder the lead and re-dress it so you can do this task with the PA Cage cover installed.

So, again no criticism of Mike intended here. I am certain had he looked at the schematic he would have seen that there is no HV dc on the NC cap. In this case incorrect information would allow you to error on the side of caution, but it is a technical hobby and we all need to employ a questioning attitude and from time to time grab the meters. Without measurement we really only have beliefs and sometimes quite firmly held. I am unaware of any manufacturers rig that uses this neutralization scheme that would have DC anode voltage on the NC cap plates fixed or movable. If uncertain easy to measure if you have a DMM or

VTVM that has a 1000vdc range.

Hello Group;

My Send/Receive switch is broken on my TS-520, I believe only the plastic paddle is broken as I can wiggle the switch and go from Receive to Send.

Do you have to replace the entire switch or can the paddle be replace without tearing out the front panel?

Thanks.

Doug,
Welcome to the world of Kenwood hybrids. The problem you have is not uncommon. More than likely, there is no problem with the associated switch. The "paddle" is held in place by two "fingers" that go into the switch body. Many time just one "finger" breaks off...and the "paddle" stays in place..but a bit loose. If both "fingers" break, then the "paddle" will usually be really sloppy...or just come off. Check with Walter Dilley at: walter.dilley"at"gmail "dot" com or the EBAY listing under item number:262234502756.
I recommend that you do NOT try and remove and then replace the "paddle in question" without removing the knobs and face plate. Now would be a good time to remove the control knobs AND the face plate for a cleaning..and then while the face plate is off...install the new "paddle."
Just my recommendation.

Terry, (and all),

The myth of HV being on the neutralizing cap is likely because several Yaesu models, (notably the original FT-101 series), did have HV B+, (from the driver tube plate & screen supply), on one side of the neutralizing cap.

Regards

Tom

To all,

I mean no disrespect to anyone. I stand corrected regarding HV being on the TS-530 TC1 neutralizing capacitor. We all make mistakes and learn from others which is what this group's all about.

Having said that and since I do a significant more work on Heathkit vacuum tube transmitters and transceivers (DX-40, SB-400, SB-401 HW-101, and SB-100 etc) verses the low number of Kenwood hybrid transmitters and transceivers, I can say that the Heathkit SB-400 and SB-401 transmitter's neutralizing capacitor does have a minimum HV of +250VDC on one lead of the final amp neutralizing capacitor which requires caution when adjusting. I have measured this voltage before so I know it's there and it's not due to a failed component. This can be seen on the SB-400 and SB-401 schematics.

Some may think when I refer to HV that I am referring to the final amplifier +920VDC plate voltage in the KW hybrids and other vacuum tube amplifiers. Not true. You can be killed JUST AS DEAD from +250VDC and less as you can with +920VDC!!! Remember, it's NOT just the voltage that kills you but rather it's the "CURRENT" as well that does you in!!! I will continue stressing the importance of using safe practices when working around high DC voltages in the KW hybrids or other makes and models of ham transmitters and transceivers. Just because you have a ham license does NOT mean you know everything!! A ham license simply means you passed a test, nothing more. It does not mean you know how to work "safely" around high AC and DC voltages. There are too many hams that are "DEAD" because many of them thought they were working safely around high AC and DC voltages until that one mistake they made that did them in!!! I will continue to stress the importance of using safe practices when working around AC and DC voltages in ham gear.

Again, I stand corrected on the presence of a DC voltage on the KW TS-530 final amp neutralizing capacitor. Thanks again for the correction.

From: Louis Wilen
Topic: 55792 Message: 55828

While I have nowhere near as much experience repairing rigs as Terry or Mike or many others who follow this forum, I would like to add this comment:

Wouldn't it just be best practice to just entirely avoid the use of metallic tools when adjusting electronic equipment?

Fine quality non-conductive ceramic and plastic tools designed for adjusting electronic devices are readily available and are inexpensive nowadays. Save the metal screwdrivers for disassembling and reassembling devices while the power is off.

Also, by using a plastic tool, you greatly reduce the risk of damaging a stuck tuning screw or slug, since the plastic tool will bend instead of tearing up the screw.

Subject: Re: [TS-520_820_530_830] TS-520SE No transmit in CW

Hello again Mike,

Okay, here is my latest update with the TS-520SE no CW transmit issue. I followed your directions and checked the CAR unit output frequencies and signal levels. Levels & frequencies were checked at the CAR units “OUT” terminal.

My frequency counter is an old B&K unit so may not be 100% accurate.

CW RX is 3394.35

USB is 3393.75

LSB is 3396.65

CW TX showed no output.

Signal level was initially about 650 mv in CW RX, USB, and LSB.

0 v in CW TX.

After peaking T1, now have about 1 volt out on USB & LSB, about 950 mv in CW RX, and still 0 v in CW TX.

So the unit stops oscillating when the radio is keyed in CW or Tune.

Control voltages at the CWR and CWT terminals appear to be correct.

At this point I’m assuming the CW crystal is going south, (or maybe the associated trimmer cap?).

I’ll contact Walter Dilley to see if he has a CW crystal.

Any other thoughts?

Thanks again for your patience and assistance.

Regards

Tom

On Nov 1, 2016 4:01 PM, "Mike W5RKL w5rkl@yahoo.com [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

George,

The final amplifier neutralizing procedure is on page 26 paragraph 6.4 "TRANSMITTER NEUTRALIZATION"

An analog VTVM with RF probe can substitute for the RF volt meter. You can find analog VTVMs on eBay rather cheap and you can build the RF probe yourself. If you have access to a 30Mhz or higher scope then use the scope in place of the RF Volt meter. Pay attention to the "CAUTION" notice in the TS-530 User manual as shown above!!

The final amplifier neutralizing procedure is also in the TS-530S service manual, page 40, step 19. I cut and pasted step 19 from the TS-530 service manual page 40.

You should not attempt to service your TS-530S without the service manual and appropriate test equipment.

If you do not have the TS-530S User and service manual, you can download them from my website at the following links:

http://w5rkl.com/wp-content/uploads/2014/04/Kenwood-TS-530SP-manual.pdf

http://w5rkl.com/wp-content/uploads/2014/04/TS-530S_Service.pdf

You will need a non-conductive screw driver to adjust TC1 inside the final amplifier enclosure. There is HV on that cap and using a metal screw driver can cause a short damaging the 530.

If you do not have the experience working around High Voltage, +920VDC, then I recommend you find a local ham who has the experience to help you neutralize the final amplifier in your TS-530S. You could easily damage the TS-530 and/or you can receive a severe shock if you are not careful. There is no such thing as a slight "tingle" shock from "+920VDC"!!!! In short there are voltages inside the TS-530 that can easily KILL YOU!!!

Hi Tom,

Based on what you have given us I think you need
to dig just a little deeper before ordering a
crystal. The important point to me is the crystal
does oscillate so I question why not in tune or
TX. It could very well be a weak crystal but it's
good practice to rule out everything else. The
difference between TX & RX on the carrier unit is
the CWR and CWT lines. They forward bias D1 & D2
respectively which effectively grounds the crystal either directly or via C2.

Before ordering a replacement crystal I would do
the following - it won't take long;

Disconnect CWR & CWT and while in CW RX connect
the original CWR wire with a alligator lead
alternately to the CWR or CWT post. If the
crystal doesn't start when you connect to CWT
then check C3, R2, L2, D2 and associated copper
traces to make sure there is continuity all the
way to C2. Perhaps C2 is open (unlikely) or you
need give TC1 a tweak. Don't be so concerned with
the actual frequency during this test. It is more
important to know the crystal starts reliably.

LSB is 3396.65

CW TX showed no output.

Signal level was initially about 650 mv in CW RX, USB, and LSB.

0 v in CW TX.

After peaking T1, now have about 1 volt out on USB & LSB, about 950 mv in CW RX, and still 0 v in CW TX.

So the unit stops oscillating when the radio is keyed in CW or Tune.

Control voltages at the CWR and CWT terminals appear to be correct.

At this point I’m assuming the CW crystal is going south, (or maybe the associated trimmer cap?).

I’ll contact Walter Dilley to see if he has a CW crystal.

Any other thoughts?

Thanks again for your patience and assistance.

Regards

Tom

The more I think of the problem and looking at the CAR Unit schematic, knowing you said the CWT DC voltage is okay, I am changing my suggestion.

As you said, the DC voltages at the CWR, CWT, and both side band pins are all good so I'm relying on that statement being true. I now think L2 could be open or have a broken lead.

If L2 is open, possibly due to a broken lead, then the DC voltage you see at CWT may be good but it's not being applied to the anode of D2 turning on Q1 oscillator and switching the output frequency to 3395.0Khz.

I've run this simple test many times on my bench using a known good CAR Unit board. I simulate an open in L2 by not applying any DC voltage to the CWT pin. This results in zero RF output from the board. Now applying +9VDC to CWT results in a 1 volt sine wave displayed on the scope and an output frequency of 3395.0Khz.
You can verify if L2 is open by using a jumper wire. Connect one end to the anode of D2 on the 3 tab terminal strip and the other end of the jumper to the anode of D2 on the CAR Unit board. If the CAR Unit board produces a 3395Khz output signal then you know L2 is most likely open, probably due to a broken lead.

Hello again Mike,

Okay, here is my latest update with the TS-520SE no CW transmit issue. I followed your directions and checked the CAR unit output frequencies and signal levels. Levels & frequencies were checked at the CAR units “OUT” terminal.

My frequency counter is an old B&K unit so may not be 100% accurate.

CW RX is 3394.35

USB is 3393.75

LSB is 3396.65

CW TX showed no output.

Signal level was initially about 650 mv in CW RX, USB, and LSB.

0 v in CW TX.

After peaking T1, now have about 1 volt out on USB & LSB, about 950 mv in CW RX, and still 0 v in CW TX.

So the unit stops oscillating when the radio is keyed in CW or Tune.

Subject: Re: [TS-520_820_530_830] TS-520SE No transmit in CW

Mike,

Okay, I made the additional voltage tests you suggested and have the following results.

To verify my baseline, at LSB and USB mode switch positions, I get approx. 8.5 VDC at the LSB and USB terminals on the Carrier board in both transmit and receive.

In CW position, I get 8.5 VDC on the CWR terminal in receive, and approx. -1.7 VDC in transmit. On the CWT terminal, I get, as expected, the exact opposite – approx. -1.7 VDC in receive, and 8.5 VDC on transmit.

In Tune position, I get 0 VDC on the CWR terminal in both transmit and receive – explains why I have no receive in Tune position. On the CWT terminal, I get approx. 8.5 VDC in both transmit and receive.

Now to your specific tests: I measured the voltages on the anodes of all 4 diodes in both transmit and receive – with the mode switch set to the corresponding positions.

LSB – (Diode D4) – transmit and receive both show approx. 650 mv.

USB – (Diode D3) – transmit and receive both show approx. 650 mv.

CWT – (Diode D2) – transmit approx. 650 mv, receive approx. -1.7 v.

CWR – (Diode D1) – transmit approx. -1.7 v, receive approx. 650 mv.

So, it appears L2 is okay, and I’m still leaning toward a soft crystal or TC2 trimmer. I also suppose C2 could be bad, but I would think that very unusual.

Of further note, when I closely watch my dummyload / wattmeter I note that on initial activation of transmit it will briefly spike output for ½ second or so. Also, as I was initially getting the radio operational again, I had quite a time finding a very small sweet spot on TC2 where CW receive came alive.

As for no receive in Tune position, I’m pretty sure other 520’s I’ve worked on did receive in Tune, so I may have a wiring problem there?? What do you thimk?

Regards

Tom

Hint: We live and die by our KW documentation which sadly isnt always what it should be. Might want to compare the large TS520S schematic with the schematic in the TS520SE owners instruction manual. It helps if you have an accurate schematic.

Looking at the large TS520S schematic ask yourself the following:

1. Where does RLR and RLT get its 9vdc?
2. Can you explain where CWR gets its 9vdc diode switching bias in CW mode?
3. Where does the movable contact of RL1 aux control relay get its 9vdc?
4. Is there a missing "Dot" on the RED bus line?

I dont know if the 520SE is designed to receive CW in Tune mode. Review of the schematic would say no as there is no Tune/CW jumper shown on S3-2, but can assure you that it does on the 520S.

Interestingly it is also very narrow passband. As if you had a optional CW filter installed. Maybe something to do with where the carrier is injected into the SSB filter? A question for another day.

Terry K9TW

From: Mike W5RKL
Topic: 55767 Message: 55839

Tom,

I measured the CAR Unit main power, BS, and all the Mode switch pin voltages.

Main board power = +8.92VDC (power is supplied from the VOX Unit "9" pin)
BS power = +8.12VDC (volt drop across diode D2)

TUNE Mode
RX = -2.6VDC
TX = -2.6VDC

CW Mode
RX = -1.82VDC
TX = +8.91VDC

USB Mode
RX and TX = +8.91VDC

LSB Mode
RX and TX = +8.91VDC

CAR Unit output frequencies

TUNE Mode
RX and TX = 3395.0Khz

CW Mode
RX = 3394.15Khz
TX = 3395.0Khz
Note the CW receive 850Hz offset frequency (3395 - 3394.15 = .850) between RX and TX.

USB Mode
RX and TX = 3396.53Khz

LSB Mode
RX and TX = 3393.53Khz

I didn't measure the CAR Unit output signal level. The typical CAR Unit RF output signal level range is from 800mv to 1.2 volts.

The TS-520 should receive in TUNE mode.

I could be wrong but I seem to recall that you are purchasing a replacement CAR Unit board from Walter Dilley. Walter is the go to man for KW hybrid parts!!!

Purchasing a new 3395.0Khz crystal for X1 (TUNE/CW RX/TX) on the CAR Unit board will be very expensive. International Crystals in Oklahoma City, OK can make one for you BUT the price will be a minimum of $50 and a 10 week lead time.

Mike,

Thanks for the measurement voltages. I will print them out and keep them on file. Your voltages and frequencies look very like mine except for "Tune" mode. Terry brings up an interesting point, I have not looked at the 520S schematic, only going by the 520SE schematic in the manual. Also, will investigate that jumper he refers to on the mode switch - if missing would explain why no voltage on CWR in Tune.
I have been in contact with Walter, and he is gathering up what I need, (I needed a couple of other pieces as well).

I will keep you and the group informed once I get another crystal or complete CAR board and install.

Thank you for your help and patience.

Regards
Tom

Here's my answers, probably wrong but what the heck.
/
1. Where does RLR and //RLT get//its 9VDC

/RLT from VOX Unit through GENERATOR Unit "RL" in TX.

RLR at the junction of R13 and R14 on the RF Unit. I'm still not sure where I'm missing where the -6VDC source through the resistor divider results in changes to +9VDC at the junction of R13 and R14, I must be missing something here but I'll keep looking.

/2. Ex//plain where CWR gets its 9VDC diode switch bias in CW mode?

/From RF Unit's "RLR".

/"//3. Where does the //moveable contact on RL1 aux control relay get its 9VDC//"/

From RF Unit's "RLT" in TX.

/"4 Is there a missing "Dot" on the RED bus line?"/

When I measure CWT in TUNE I get +9VDC. If one looks at the schematics, which I have all morning, there's no way +9VDC is present on CWT in TUNE mode by the way the schematic wiring, Mode and Function switches show. Therefore, I think the missing "Dot" is where the RL1-4 BLACK fixed terminal wire "crosses over" the +9VDC RED buss and connects to Function switch S2-1 "FIX R" position. That is the only CWT can have +9VDC in TUNE mode.

My answers could be wrong.

I have looked at TS-520S, TS-520SE both operator and service manual schematics plus the high resolution TS-520S schematic and they all have the same Mode switch CAR Unit and RL1-4 wiring. I have measured the CWR voltage at the Mode switch "White with Orange Strip" wire in TUNE TX and RX, both are -2.7VDC. Change to CW Mode, same wire at the Mode switch, changes to +9VDC in RX but drops to -1.87VDC in CW TX. I suspect there's an internal Mode switch shorting connection that makes the connection to CWR in TUNE mode that is not shown on the schematic. I don't see a jumper wire nor do I have a TS-520 model switch so I can't verify that so I'm only "assuming" there's some internal connection in the Mode switch. I do believe the schematics are wrong which has puzzled me during the time I have tested the 2 CAR Unit boards I have.

55844. TS830s just a few small issues

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-11-05 19:22:09 UTC
From: Riley Hart
Topic: 55844 Message: 55844

Hi! I hope this gets thru, when I submit this from the 'start a new topic' link, when the webpage opens, it says not authorized.
My rig has a couple of problems I'd like to fix. Am not a great schematic reader or troubleshooter but have repaired a few things on the rig, so far new hv caps and the replacement unit for rl-1, and if I can figure it out, would be great:
The transmit tunes nice on 40m and that's where i predominantly use the rig but just installed a new antenna and can work 80m now. With swr tuned flat, on 80m, here is problem; i can tune up okay in tune position, but when I switched to cw and key the rig, i can't get a peak power level with the load control...as it is advanced clockwise, the power continues to increase, without a spot where it peaks and then goes down again. Get the dip on the ip no problem. Have replaced the bs connector going into the final cage already, and no bs problems i am aware of. This may be result of operator error, as i recently left the rig in transmit with no load(had key line open) and it blew a fuse. It's okay on 40m though, so don't think anything is damaged. So any ideas?

Problem 2.:
I have developed a rough tone on my cw notes on receive, and thinking I might replace some of the other caps that I didn't do when I put in the new hv caps. Does this sound like a logical step?

Thanks and 73,
Riley wd4dkv.

I should have looked at the first TS520 schematic!!!!
If one looks at the "TS-520" schematic, it shows a jumper between TUNE and CW on Mode switch S3-2.. Relay RL1-2 routes +9VDC from the FIX CH AVR "9: terminal to CWR in TUNE and CW mode RX. Switching to TX, RL1-2 reduces CWR well below 9VDC and applies +9VDC to CWT in CW TX.
I have the TS-520 operator's manual on my website
http://w5rkl.com/wp-content/uploads/2014/04/TS-520-operators-manual.pdf
The main schematic is on page 51 and can be zoomed in, with clear display.

Mike:

Look at the TS520 schematic again. RL1-2 is RIT.

Look at RL1-4 contacts.

What is missing on the TS520S and SE schematics in addition to the "dot" at RL1-4 is a line dropping straight down from the 9v lead leaving the AVR board that is shown only turning upward. If you draw a red line down from that point to the 4th horizontal line from the bottom of the schematic you will heat up Pin 9 of the Ext VFO and heat up the movable contact of the Function Switch S2-2. Without that line all of that associated 9vdc is just floating. No 9vdc for Carrier osc switching diodes and no 9vdc for RLR and RLT.

55847. TS520S Schematic Errors

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-11-05 23:42:25 UTC
From: wagstw46@...
Topic: 55847 Message: 55847

I think things were getting messy on the TS520SE thread so decided to send new post.

I submit that there are 3 additions that need to be made to the TS520S schematic.

1. Draw two black connection DOTs. One at the 9vdc line at the Mode Switch deck area so that the movable contact of RL1-4 has 9vdc on it. For the other dot follow the line from the bottom of C29 to the left and up and place black connection dot on the 2nd horizontal line it crosses. See the TS520SE schematic in Owners Instruction manual. Mark up the TS520S to look like the SE at RL1-4 and the Mode switch deck area.

2. Draw a jumper wire between Tune and CW positions on S3-2. Now aligns with having Rx mode in Tune. In Tune we are using CWT for Rx and Tx and that is why the Passband looks like the sweep that I provided. You are inserting the carrier oscillator off the IF filter center frequency (Fc) producing the narrow response.

3. Coming out of the 9vdc regulated terminal on the AVR board where the drawn lead goes upward make a Tee connection and extend an additional Red line downward to the 4th horizontal line from the bottom of the schematic. Now will have 9vdc regulated to Pin 9 of the Ext VFO jack and 9vdc regulated to the S2-2 function switch wiper. Without this line all is just floating.

Terry K9TW

55848. Re: [TS-520_820_530_830] TS520S Schematic Errors

Terry and others,
I found those corrections/connections you mentioned, on the TS-520 schematic. For me the TS-520 schematic is much easier to follow and see where the voltages are coming from and going to. I'm going to see if the local printing store can enlarge the TS-520S and TS-520SE schematics so I can annotate the additions.

RL1-4 on the TS-520 User manual schematic is at a different place on the schematic. The NB Unit is in the center of the schematic. Looking to the right of the NB Unit's "OUT" terminal is where RL1-4 is. Looking at RL1-4 you can easily see how 9VDC is applied to RL1-4 moveable element from the FIX CH AVR Unit "9" pin. You also can easily see how 9VDC is applied to Function switch S2-2 so Pin 9 of the REMOTE VFO socket has 9VDC with Function switch S2-2 in the VFO, 25, RMT, and .FOX positions.

It also shows how Mode switch S3-2 applies 9VDC to CWR in CW mode (S3-2 has a jumper between TUNE and CW positions). The 9VDC comes from FIX CH AVR "9" pin up to RL1-4 moveable terminal to bottom fixed terminal then "UP" 6 horizontal wires then to the left along the top of the NB Unit then down a zig/zag then to the left along the top of the CAR Unit then down and then right to Mode switch S3-2 wiper.
This is not the first schematic error I have come across in 48 years of being a ham and probably won't be the last.

From: wagstw46@...
Topic: 55847 Message: 55849

Yes good idea to blow them up, but as you know you need a correct TS520S schematic as there are some significant changes from the TS520 to the TS520S. So annotating the 520S is the way to go.

So we need a good TS520 and a good TS520S schematic. Cant troubleshoot a 520S/SE only using the 520 schematic.

I have all the schematics blown up and I used a local Fed Ex print shop. I downloaded all the best quality schematics I could find to memory stick and took it to Fed Ex. I had them make a set of 11x17 of the PC boards , one 24 x 36 schematic , and one 18 x 24 schematic and laminated it. Didnt laminate the biggest as I want to be able to mark on it. Not cheap but invaluable especially with these old eyes!

55850. Hybrid Net Update (November 6, 2016)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-11-06 19:21:05 UTC
From: Mark Gilger
Topic: 55850 Message: 55850

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by me, WB0IQK. There
were 18 stations checking in under fair band conditions.

We had the following number of radios checking in.

3 running TS-520(x)
4 running TS-530(x)
2 running TS-820(x)
5 running TS-830S
0 running TS-510
0 running TS-511
0 running TS-515
0 running 599 twins
0 running TS-900

I was running a TS-830S with an Drake L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
12 stations checking in fairly good band conditions.

We had the following number of radios checking in.

2 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
4 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
1 running TS-900

I was running my TS-830S + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

55851. Kenwood TS820s

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-11-06 21:06:12 UTC
From: n4jhy@...
Topic: 55851 Message: 55851

A friend laid a decent condition TS820s on me today.

Up slowly on a variac, and am listening to it now.

Needs- VFO cleaned/lubed, and the digital readout is just showing two dots. I see a lot of info on this problem.

Transmitter will just make 100 watts (tested on 40 and 80).

Where I need a bit of help with it that bias shows to be 80 mills, and turning the bias setting pot makes no difference in the idle current. 80 mills.

Thanks y'all.

Bruce N4JHY

So I've just bought a 2nd hand TS-830 to keep alongside my trusty TS-530 and am going through a check and alignment.

One thing that is interesting is that the analogue scale is out by around 100Hz or so compared to the digital readout. The end stop marker is correctly positioned so I am assuming that maybe the digital side is actually what is out of alignment.

Anybody have a procedure for checking and re-aligning?

73

Brian

Brian,
The Service Manual tells you on Pg. 34 Step 7 "VFO, RIT, FIX CH check and adjustment. If you do not have a Service Manual, you can download on from: w5rkl"dot"com (Mike-w5rkl is a group member), or n6wk"dot"com (Gordon-n6wk is now SK)

Brian,

Do you have and have you read the TS830 operator manual where it discusses the analog dial? If you do not have the TS-830 operator manual then you can download it from my website at the following link:

http://w5rkl.com/manuals/

When the page comes up, scroll down to the Kenwood listing and click on the TS-830 operator manual link. The manual is 36meg in size and may take a minute or two to download.

Go to manual and Adobe reader pages 21, figure 4.17 "Analog Dial Calibration", and paragraph 4.7 titled:

"/ANALOG DIAL CALIBRATION/"

which explains how to calibrate the analog dial. Also read the comment on the same page that says:

"/NOTE//
//For exact frequency, read the Digital Disp//lay"//
/
The analog dial will not always follow the digital dial "exactly". Therefore, when you tune the VFO up and down the bands and find the analog dial does not follow the digital dial exactly, don't think there is something wrong with your 830. The analog dial will not always follow the digital dial.

I hate to say this, but I messed up. I hate that term, but it is true.

While trying to adjust the bias control on the rear of the radio, I had the meter in the ALC position rather than the Ip position.

For some reason, when I go to xmit, with the meter in ALC, with no modulation, the needle rises up to almost halfway up the ALC black area.

As far as the bias adjustment, now, with the meter in Ip, it adjusted with no trouble to the 60 ma level.

Any idea what is causing the ALC meter to be so high with no modulation.

Otherwise, the radio works well with about 110 watts PEP, and good xmit audio reports.

Thank you, Bruce N4JHY

Thanks very much for the help Joe,

I've downloaded the service manual from the source you suggested and looked at the procedure.

Looks reasonably straightforward but I've learned from experience that sometimes things that look easy are rarely easy. Still, time to get her open on the bench and have a go... fingers crossed...

Aside from this small issue, everything else seems to be generally ok, She appears to be giving close to full output and not dropping over time so looks like the driver and output tubes ok.

Brian,
 Glad to help, but you must also remember that the analog dial will not track exactly to the digital readout..but when properly adjusted, should be close. Mike-w5rkl also states must know info. Watch the gear train of your VFO sometime while it's being operated...quite a piece of engineering

When you speak in to the mic does the ALC indication go up scale from there and then slowly drift back downward? Like you are looking at an RC time constant?

If so, most likely you have bad molex connection on RF Board RF-3. More than likely with Pin 4 and Pin 6.

Sadly the 820 has real issues with its molex connectors. Problems include:
1. Bad crimp on the spring temper wedge crimp connector to its lead wire. Some radios used solid lead wire and others used stranded wire. More problems with the solid lead wire crimps.
2. The spring temper wedge on the crimp connector is bent up and not making good contact or the wedge has broken off and is just floating inside the connector body,
3. The connector bodies were not fully seated flush with the board and held there during soldering.

Number 2 is most common problem.

Go to page 37 of service manual to see the crimp connector. Need thin blade screw driver or soldering aid to release the lock tab.

Carefully unplug RF-3 and with good lite look into each hole (opposite the lead wire insertion) and see if you can see the tapered wedge fully in the window. Gently press upward on each wedge with small pointed tool or thin bladed screw driver. Should be able to feel and see the spring action. If it pushes upward and doesnt return to fill the window it is bad.

Carefully release the lock tab and press wedge terminal out toward rear of connector body and then pull gently on lead wire or terminal barrell with miniature needle nose to completely remove. If the wedge is collapsed can sometime just touch it and it will fall off. If there is no wedge then tip the connector body down and tap on it and broken piece will fall out. Hold over a rag or away from the RF board so the piece doesnt fall down among components on the board.

Will have to cut off at least an inch and butt splice/heat shrink on a lead wire that has good tapered wedge crimp on it. Contact Walter Dilley to harvest a few for you or buy wire harness from him. Will need plenty if you plan to keep your TS820S working especially if one of those fellow who likes to routinely pull and clean them.

Other option is to strip lead wire and tack solder it directly to the PC board or molex connector. I hate that.

RF-3 Pin 9 and Pin 10 (FG and VR-2) are also very common problems and if bad you will have some very pretty brite orange glowing Final Tubes!

So if it were my rig I would also release 9 and 10 and inspect and make sure good wedges and good crimps on both. Have to ring out lead wires to make sure crimps are good. After renewing measure cut off bias at Control grids of the finals and make sure it is there and

stable.

As to why high resistance connections at Pin 4 and Pin 6 causes standing ALC indications and slow decay during modulation you are introducing high series resistance into a dc power supply (ALC buss) that is already by design a high Z source (fed thru a 2.2 meg resistor) and cannot support any load current. If you increase the impedance then the ALC bus voltage will be very easily pulled down just by capacitors in the RC time constants and parasitic capacitance causing the meter to read up scale seeing lower than nominal 3.2 to 3.5 vdc RF-1 voltage (depending on where you have set it).

I have TS820S on bench now that had 5 broken off spring temper wedge crimps between the RF and IF board molex connectors. That included bad Pin 6 on RF-3. That can make for some real tough intermittent troubleshooting.

You are in for hours of fun until the scale is reasonably close. The main problem is that the two adjustments L3 and TC1 interfere with each other.

Set the lower frequency with L3, turn the VFO up, set the upper frequency with TC1, check lower frequency again... its off.
Set the lower frequency with L3, turn the VFO up, set the upper frequency with TC1, check lower frequency again... its still off, but better than before.
[...]

Da capo al fine, as the Italian says. After 10-15 rounds I had my VFO scale reasonable close to correct frequencies. Additional fun can be had if you set the lower frequency with TC1 and the upper with L3 (this is easily possible, ask me how I know). Then the offset at the other end will grow instead of shrinking...

Martin DB2MJ (who finally decided that close is good enough and a digital readout is a mighty fine thing)

PS. It doesn't work if you open the VFO for better access... your adjustment will be fine until you close it again. BTDT.

55861. TS-530S Low Mic Input

Thank you for the help last week with the "No ALC" problem in my TS-530S. I have replaced R111 on the IF Board with a Vishay 1% 470 ohm metalic film resistor and all is well -- almost.

The new problem is that I have to set MIC GAIN to about #9 to get normal ALC swing output, whereas I used to run with MIC GAIN at #4 for get normal ALC swing. This behavior is pretty much the same on 10M through 80M. At MIC GAIN #4 now I get about 1/4 the power out that I used to get with my external wattmeter set to display PEP. Similar output with wattmeter set to AVG and humming into mike. I am using a Kenwood MC-50 mike in high impedance mode, which is exactly what I've been using since the rig was new. I have a spare MC-50 so I tried it and I get exactly the same behavior. Just for kicks, I tried low impedance mode on the mike and saw no appreciable difference.

Recall that the rig worked fine on both SSB and CW before R111 failed. I have owned this rig since new so I know that nothing improper has been done to it.

I have full ALC on all bands in CW mode, although 10M requires the CAR control to be moved to 3:00 to get nearly full ALC. Oh all other bands, I can get ALC even to the right of the ALC segment on the meter. So my driver is a bit weak, but still fully usable. HV is 900v in SEND, and drops to about 820V when the rig is keyed in CW mode. IP is normal, 265 ma. Idle IP is 60ma in SSB. Power is 95W on 10M CW, 120W CW on 15M, 130W on 80M CW (although of course, I don't normally set CAR high enough to let the power get that high.) Output power does NOT drop off at all when the rig is keyed CW for five seconds. (I don't like to key for longer than 5 seconds.) Of course, this is all using a good dummy load. So from a CW point of view, the driver tube appears good.

Transmitted audio sounds good listening to it with another rig.

I have a function generator in case injecting some audio somewhere would be helpful.

Maybe I should just try a new driver tube first. Thoughts?

Any ideas as to why I suddenly have to turn up the mike gain to get full ALC swing?

Hang on, I may have found the problem.

I had gotten into the habit of always operating with the speech processor enabled because of the lousy band conditions nowadays. But when I was testing (below), I didn't have the processor on because I had forgotten to turn it back on after working on the rig. Of course, as soon as I realized that I had it off I turned it on and now I get normal ALC with the mic gain set at #4.

So there probably is something a bit off in the rig, maybe the driver tube is weaker than I thought or maybe something else. I think that I really should get a bit more ALC at mike gain #4 with the speech processor off. I've been running with the processor on for so long (since all stations say I sound better that way) that I wasn't even aware that there's a problem, which has probably been masked by keeping the speech processor on.

I guess I'll procure a new driver tube as the next step. In the meantime, any thoughts are welcome.

The Mini-push button switches in the 530/830 series are getting to be a problem. Often processor will work (button depressed) , but straight audio will not work (button released).

Try multiple exercising including pulling outward on the grey actuator button and moving it side to side at same time.

No good way to get any meaningful amount of contact cleaner into the contact area especially on the 530s. On about every other 830 that hits the bench I have to drill a small hole in the rear corner of the switch metal housing with a pin vise and series of small letter drills that allows injection of contact cleaner. Must be done very cautiously so not to allow bits to penetrate too far inside switch body.

I dont know of any source of NOS or like for like new sub switches.

Lastly, I wouldnt be loading to 265ma. I know that is max allowable, but no benefit on receiving end.

Alignment can be very sensitive to the position of L4. Sometimes someone has driven slug deep into the former or backed it out to near top of shield can.

If cant get it to come in at 50 and 450 then try at 100 and 400.

I always clean both endboard and outboard rotor shaft wipers first and back off and re-snug the PC board mounting screws. Sometimes find them just barely finger tight.

Set 9vdc regulated first and then set VFO RF output and then align with L3 and TC-1. Sometimes they come in easily and other times a challenge.

Of course dont attempt until warm up drift has settled out.

George,
Before doing a "shotgun" replacement of the driver and/or the final amp tubes, go to Ken Kemski's web site: k4eaa"dot"com and check the info regarding the signs of failing drivers/finals. Your rig is a real good tube tester versus just testing in a tubes tester, this subject has been discussed at great length, and this subject is available IF you do a search in the "conversations" section of the group's home page...which will yield LOTS of "conversations."
You need to ask yourself...what could have changed to cause the change? Different antenna...rain, snow, broken element...tuning into a dummy load versus an antenna..etc... visually check to see IF any of the couplers are slipping on their respective shafts,have cracked areas by the set screws(very common) especially the bandswitch coupler

George,

Have a look on RF board, there you will find the drive shaft which has chain going to nylon gears. Basically they are of similar composition as the shift couplers. They tend to crack where the grub screw goes through the body of gear, or the grub screw has come loose. If they are cracked Gregory, NR6C, has reproduced using better materials.
Start with the simple things first and just be methodical in fault finding.

Are the receiver off air signals and/or marker signal also weak on those bands? If so, then most likely root cause is dirty or bad Bandswitch contacts on the red/brown vertical boards.

Try in place cleaning first. I use small amount of D100L applied with artist brush or mini-applicators available from MicroTools. Let it soak good and exercise the switch multiple times. I then apply D5 and repeat switch exercising and then blow off with compressed air. May have to repeat this several times.

If this doesnt work then have to pull the RF board and remove the wafers and silver polish and solder rivets. See W0NTA website for procedure or contact Dick Housden to see if he will rebuild for you.

Your 3.5 mhz plate current dip has nothing to do with the RF drive or the Drive control knob position. If all the other band plate current dip positions are correct then likely have lost 80 meter fixed padder cap that is switched across the Tank capacitor or a bad/dirty contact on the S22-2 deck.

If the other bands dont dip close to the marks on the white arc then most likely have a loose fiber shaft coupler at the PA cage. Caution.... dont over-tighten the lock screws as the cap shaft is fibre and can crush it.

Topic: 55869 Message: 55869

Hi there group, I acquired a ts-830 about a year , two actually, I gave up trying to fix them. I sent one of the radios off to a very respected repair fellow in NJ. The radio has worked great, and still does in that I have full power on all bands. However, I used the radio one day and all was great, the next day I have very low volume through the internal speaker. I used headphones and the volume seems low with those as well. I have to have rf gain all the way up to hear background noise. It still seems to receive ok, you just can't hear the conversations very well.

What have I done to find the problem you ask, nothing. I am very hesitant to remove the cover based on my previous experiences.

Is this a common problem? Easily fixed sometimes? All I have done is plug and unplug a headphone jack into the external speaker plug a few times. It had no effect. Covers have not been removed.

Advice is appreciated.

While stupidly trying to tune up my 820S at full power, I raised my SWR way too high and toasted something in my rig. Zapping sound, then a slight odor for a few minutes. My output (as measured on my antenna tuner meter) dropped to about half of what it was.

Some quick tests showed that in USB mode I now have only 35ma bias current instead of my previous 60ma.

With the rig's meter in HV, I have only 450 v instead of the usual 800v.

I opened the rig up and tested voltages on the Final board...all seem to be close to the expected readings shown on the schematic for that circuit.

No visual clues inside the rig of anything that looks cooked.

I'm getiing what, in my opinion, seem to be strange voltage readings at various locations on the Rectifier board, but the schematic doesn't really indicate what the expected readings should normally be.

I have very little in the way of test equipment...mainly just a cheap digital volt-ohmmeter, and an older analog volt-ohmmeter.

I'm sorry if this topic has been covered before (I can't imagine I'm the first one to mess up like this), but I have a very difficult time navigating these group threads, and I'm not sure what kind of key words would be helpful in a search.

I'd appreciate any help the group can provide.

Recently I got a TS-520 from a seller who was so disgusted with it that he sold it to me for less than I offered!! I could not pass on that deal. The VFO was inoperative, the dial frozen, and the analog display was replaced with a digital display that only flickered. Well now the VFO and dial (and radio!) are working but I can't figure out the digital display (an unmarked and unidentifiable commercially made one) so want to return it to the original analog display. Does anybody have spare VFO dial sub-plate R20-0287-04 or the dial scale B20-0287-04 or can give a lead on where to find one? Any help would be appreciated before I start trying to make a homemade dial. I would like it to look as original as possible now that I got it working. Thanks.

Thanks Terry

So far, with a power meter attached, I am able to tune the rig to the correct final power. I am wondering if something may be slipping on the shaft, although, it does not appear to be. Now I tuned the rig, and the capacitor settings on the plate show correctly. Go figure. Any more thoughts???

Hi Jeff,

It is unlikely you will fix the problem without taking the covers off. If you are not confident in your troubleshooting abilities you could send the radio off for repairs. However, based on what you have told us you should be able to do a few simple checks to at least localize the problem. You should have a service manual and circuit for your radio and be able to conduct a few simple measurements.

You can find the service manual here
https://groups.yahoo.com/neo/groups/TS-520_820_530_830/files/MANUALS/TS-830S/

You can find an excellent large format schematic here
https://groups.yahoo.com/neo/groups/TS-520_820_530_830/files/MANUALS/

Use the circuit and service manual to identify the various connectors and sections of the circuit. There is a block diagram and board overlay in the service manual that will help you identify connectors and important components. According to your description it seems the problem is before the headphone jack.

Start your troubleshooting by understanding the audio path and the AF unit. Because you can hear signals (albeit low) I expect the low level audio section is ok but there are a couple of tests you can do without pulling off the covers.

Action - when you adjust the AF GAIN from min to max does the volume level vary smoothly? If it does not vary smoothly (jumps) or does not vary at all, I suspect you have either a broken wire/connection or the AF GAIN pot VR3-2 is faulty in some way.
Action - check CW sidetone. Is it louder that the RX audio. Does it vary when you adjust the AF GAIN control?

Now is the time to remove the covers.

On the AF unit find Q3 and follow the audio signal AV1 through connector 2 pin 2
This goes down to VR3-2 (AF GAIN) then returns back to the AF unit as signal AV2 to connector 2 pin 1

Action - check the continuity of all connections for connector 2. Carefully remove and reseat the plug in connector 2.
Action - check that VR3-2 is intact. It should read around 10K ohms across the outer pins and the resistance between the wiper connection to either end should be somewhere between zero and 10K ohms depending the adjustment of the control.
Action - check continuity of the wires carrying signals AV1 & AV2 to

connector 2 on the AF unit.
Action - If you have a 'scope follow the signal along to confirm it
is not getting lost along the way.

On the AF unit you can see that IC Q4 is the audio output amplifier.
Signal AV2 is the input to Q4. The output audio goes from Q4 pin 10
via C34 and L1 to connector 4 pin 6 where it becomes signal SP.

Action - check the continuity of all connections for connector 4 but
specifically for pin 6. Carefully remove and reseat the plug in connector 4.
Action - If you have a 'scope check for a signal at pin 10 of Q4 and
subsequently at connector 4 pin 6.

Follow the heavy black line (signal SP) to the Phone Jack. You can
see that this signal then goes to the external speaker jack and
finally to the internal speaker.

Action - check continuity from connector 4 pin 6 to the headphone jack.

If you haven't identified the issue yet then you'll have to dig a bit
deeper. I would start by troubleshooting the AF amp Q4 and
surrounding circuitry.

Good luck and as always please remember to tell us how you resolved
your issue. There's nothing worse than reading a whole lot of
suggestions and never learning of the outcome.

Regards

Lou

1-- Hello fellow Kenwood users. I am wondering if in the CW mode the reading that show in the ALC position is related to grid current
of the final amplifiers?

2-- I have other radios that the idling plate current for a pair of 6146A tubes is 50 ma that is what the data sheet calls for the 6146 A and B.
The instruction manual says set the bias for 60 MA in the SSB mode if I do that the idling plate current in CW mode is 70 MA.
I have the idling plate current set at 50 MA. Radio works great. If I look at either of the SSB modes the current is 40 MA.
Strange setup, is this normal for Kenwood Hybrids?

1. YES---ALC indication in Tune or CW when loading and ALC indication in SSB mode when modulating, and ALC indication in CW Mode when keying is the result of the PA tubes control grids going positive with respect to the cathodes on the positive going half of the RF drive envelope (must overcome the -60vdc dc offset that operating bias presents). Grid current ranges from approx 35ua to 45ua. That is micro-amperes and not milli-amperes. Easy to measure if interested.

2.You set the zero signal plate current to 60ma in SSB mode with the mic gain full CCW (so nothing coming down the mic line to the Balanced Modulator). Two most common levels for a pair of grid driven 6146 tubes in Class AB-1 depending on manufacturer are 50ma and 60ma. Those who use 50ma most commonly have lower Plate voltage and may have been designed for 6146 series tubes with 25 watts plate dissipation. Are 6146B and S2001A tubes are rated at 35 watts. You are setting the Q-point on the load line for Class AB-1 linear operation. This level is always a trade off between most linear operation (low IMD) and final tube plate dissipation. Eimac Care and Feeding of Tetrodes has good discussion on this.

I have run 2 tone test and looked at IMD on Spectrum Analyzer and varied the resting plate current from 50ma to 70ma and very little difference in 3rd order levels.

Go to my website to read about what ALC is and what is needed to produce it.

I recommend following the instructions in your operating instruction manual. Unless field experience over long time proves that the KW design engineers didnt know what they were doing I like to error on their side.

From: Rene de Wit
Topic: 55879 Message: 55883

Hello Joe,

That is correct, I have old 6146B tubes in my TS-530S, and my idling current SSB is 70mA ,and 80mA in CW mode.

So the difference is 10mA between SSB and CW.

I have to replace the Tubes with new ones, output is about 80 Watts. But also my voltage is just 750V

I have also 2 Kenwood TS-830S, with new HV Caps and their voltage is about 900V

73`s,

Rene, PA7R

Subject: [TS-520_820_530_830] TS-530SP Questions

1-- Hello fellow Kenwood users. I am wondering if in the CW mode the reading that show in the ALC position is related to grid current

of the final amplifiers?

2-- I have other radios that the idling plate current for a pair of 6146A tubes is 50 ma that is what the data sheet calls for the 6146 A and B.

The instruction manual says set the bias for 60 MA in the SSB mode if I do that the idling plate current in CW mode is 70 MA.

I have the idling plate current set at 50 MA. Radio works great. If I look at either of the SSB modes the current is 40 MA.

Strange setup, is this normal for Kenwood Hybrids?

73 to all, Joe WA3CKA

Topic: 55879 Message: 55884

It is not RIGHT. It is however very common. Very easy to correct.

The reason that you are seeing 10ma more zero signal plate current in CW mode (with the CAR LEVEL pot full CCW) is because you dont have the Balanced Modulator carrier suppression properly nulled.

So with the Car Level Pot at full CCW you have no bias voltage to the BM ring diodes and with proper carrier null adjustment should see same level of resting plate current in CW as you see in SSB. With the carrier improperly nulled you are supplying small level of RF drive to Final tube control grids causing plate current to flow. So the Ip level you are seeing is combination being produced by bias voltage level and RF drive. So in CW mode you dont have true "zero signal" plate currrent. Some call it idling current, resting current, quiescent current etc. I like zero signal. That means no carrier output from the BM causing plate current to flow. That is why they have you adjust it in SSB mode.

While monitoring resting plate current in CW mode with CAR pot full CCW try adjusting either VR-4 or TC-1 for a minimum plate current. Should now match where you have set it in SSB mode with Mic gain full ccw. Best to do the adjustment as directed in Service manual to get as close to balanced null as you can between LSB and USB.

This is a very common problem. Just a matter of proper alignment. If you think this is normal or right ask yourself why would KW have resting plate current higher in CW Mode than in SSB mode? If anything you would want it lower going toward Class C on the transfer curve. Sometimes these kind of things can occur by what I call accidental design, but this is not the case here.

On another note. The main difference in ALC action in CW mode compared to SSB mode is the ALC time constants. A FET switch is employed to switch in different RC time constant in CW mode. Approx 22msec attack time in SSB and approx 4.7msec in CW mode. This is done to shape the CW keying waveform leading edge and to limit spurious sidebands and bandwidth.

55885. Hybrid Net Update (November 13, 2016)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-11-13 20:23:18 UTC
From: Mark Gilger
Topic: 55885 Message: 55885

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by Jimmy, WB2KNR. There
were 25 stations checking in under fair band conditions.

We had the following number of radios checking in.

6 running TS-520(x)
3 running TS-530(x)
4 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running TS-515
0 running 599 twins
0 running TS-900

He was running a TS-520 with an SB-200 amplifier.

The Sunday net was run by me, WB0IQK. There were
24 stations checking in fairly good band conditions.

We had the following number of radios checking in.

8 running TS-520(x)
2 running TS-530(x)
2 running TS-820(x)
6 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830S + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 ☐ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins
Nov. 2015 ☐ Oct 2016 Saturdays total 807 check-ins, Sunday total 628 check-ins

November 2016, Saturday net total = 43, Sunday total = 37 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Date: 2016-11-14 12:54:10 UTC
From: n4jhy@...
Topic: 55887 Message: 55887

I see that there are two relays in a TS820s?

One on the "Relay Unit" Board. I believe this one is soldered onto the board.

And one under the chassis, in the rear, under a metal shield, near the final tube board.

My question is about the one in the back, under the metal shield. Is this a plug in relay?

I get the feeling that it needs a contact cleaning.

Thanks for the help with this question.

Topic: 55887 Message: 55888

Bruce,

Did you try pulling up on both relays to remove them from their sockets?

Both relays in the TS-820 are plug in 12VDC 4PDT relays.

The relay that plugs into the RELAY Unit board, located below and the middle of the chassis, is the control relay that switches various circuits between RX and TX (RL-11, RL-12, RL-13, and RL-14).

The relay between the FINAL Unit PC board and the rear panel is the T/R relay that switches the antenna between RX and TX (RL-1), switches pin 4 on the Xverter socket to ground (RL-2), switches the meter between RX and TX (RL-3), controls linear amplifier relay switching (RL-4). You can see these connections for both relays by downloading and studying the TS-820 high resolution schematic by clicking the following link.

Thank you Mike for the info on the relays. I have been into this 820s a bunch of times since I bought it 2 weeks ago, but have forgotten to look closely at the relays.

Also, thanks for that hi-res schematic. That will come in very helpful as I try to deal with an ALC problem with this radio.

The ALC, when I go into xmit with no modulation, goes up about halfway on the ALC scale on the meter.

The mic gain control has to be run at about 7-7.5 for proper modulation D-104 and MC60 hi imp).
The ALC meter advances with modulation, and output PEP is good (110-115 watts).

Thanks again for your help on the relays.

73, Bruce N4JHY

55890. TS 820s ALC trouble

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-11-14 16:13:44 UTC
From: n4jhy@...
Topic: 55890 Message: 55890

On this TS820s that I bought 2 weeks ago I have dealt with several problems. Most importantly, with Terry's help, I got a non-functioning DG-1 working. Hurrrrayyyy!!!!

My last issue to deal with is an ALC problem with this TS820s.

When I go into xmit, with no modulation, the ALC meter goes up to 50% of the ALC scale.

I have to have the mic gain control at 7-7.5 for fully modulate this radio to its 115 watt PEP level.

The ALC meter does move up on voice peaks, and slowly falls back to the 50% indication between words.

The radio has a new driver and final tubes. Finals have been neutralized.

Terry suggested checking the RF3 connector females to the RF Unit board, and they are fine.

The radio is fully usable as it is, but this raised ALC indication does bother me.

Bias to the finals is good too in all conditions.

I guess I will have to completely draw out the ALC circuit to fully understand it.

Any suggestions would be most appreciated.

Thank you, Bruce N4JHY

Just remember that any time the ALC indication or AGC meter indication goes up scale the ALC buss or AGC buss voltage is going down. So you are looking for cause of the ALC buss voltage being pulled down.

Both busses are supplied thru RF-1 reference voltage and supplied thru 2.2 meg resistor making them by design high Z power supplies that cannot support any load current. All they normally see is the high impedance presented by Gate 2 of the the dual gate mosfet gain controlled stages and the AGC and ALC time constant capacitors. Rare for these caps to be leaky, but possible.

Also, Q5 ALC amp transistor could be leaky, but rare.

Also, R44 2.2 meg resistor could have gone high but again rare.

Most common failure on the TS820S is bad spring temper wedge molex crimp connector introducing additional high series resistance which makes buss even more sensitive to any loading. This is why I suggested releasing molex crimp terminations on Pin 4 and Pin 6 at RF-3 and make sure wedge hasnt lost its spring temper or isnt broken off and floating inside the connector body. Common problem on the TS820 rigs.

Topic: 55887 Message: 55895

An excellent caution.

I very seldom clean any KW hybrid relay contacts mechanically. Easy to bend movable contact leafs/fingers, change contact wipe, and/or remove contact flashing. I dread seeing TS530 rigs as many owners have damaged the Fujitsu FBR solder in Ant TR relay trying to clean mechanically.

Electrical cleaning is the safest and easiest method for cleaning the TS530S PC board mounted Ant TR Relay. Easy to see the dc path and inject current into the SO-239 connector and to heat up the closing coil. I remove the fan as need to remove its motor bushings for lube. With the fan removed have good access to get your power leads connected.

I use 5vdc or 6vdc current limited to one amp. Only because I have bench supply with these outputs. Can also use 12vdc or ac. If no bench supply Dollar Store 6vdc lantern batteries. Just make sure current limited. Certainly no more than 2 amps. No need to remove lexan relay covers. Just connect dc supply across each NO and NC contact and cycle the relay 10 to 20 times. I also measure resistance before and after. Should see no more than resistance of your meter and its leads. Maybe 0.1 to 0.2 ohms. Better way to measure is mv drop and should be around 100mv, but most folks wont do this as more time consuming.

I find electrical cleaning easier, faster, less chance of damage, and last longer than chemical/manual cleaning.

Use it on pulled MX-2P and MH4P relays as well as the in place TS530 FBR.

Subject: Re: [TS-520_820_530_830] TS-520SE No transmit in CW

Hello again to the group.

Okay, to put closure on the TS-520SE thread I started, I received a replacement CAR board from Walter Dilley, (Walter, you are THE MAN). Walter has been invaluable in helping me bring numerous KW Hybrids back to life, and is a true gentleman.

At any rate, rather than just swap out the CAR board, I decided to just replace the CW 3395 crystal to see if my original diagnosis was correct. After a slight re-peaking of the associated trimmer cap, I now have full output in CW, AND receive in TUNE.

As Terry correctly pointed out, receive carrier in TUNE is activated by the CW TX line, which was why there was no receive in TUNE.

A very special thanks to Mike, for his detailed descriptions, measurements, and suggestions.

A further thanks to Terry for pointing out the schematic omissions.

Finally, thanks to all in the group for your help and suggestions. This is fine group of very knowledgeable people, which has been most helpful to me over the years in solving KW Hybrid problems. Hopefully, someday I can contribute as well as receive advice.

Recently I got a TS-520 from a seller who was so disgusted with it that he sold it to me for less than I offered!! I could not pass on that deal. The VFO was inoperative, the dial frozen, and the analog display was replaced with a digital display that only flickered. Well now the VFO and dial (and radio!) are working but I can't figure out the digital display (an unmarked and unidentifiable commercially made one) so want to return it to the original analog display. Does anybody have spare VFO dial sub-plate R20-0287-04 or the dial scale B20-0287-04 or can give a lead on where to find one? Any help would be appreciated before I start trying to make a homemade dial. I would like it to look as original as possible now that I got it working. Thanks.

55901. TS-520 with voltage on cabinet

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-11-15 12:51:34 UTC
From: dan8barb@...
Topic: 55901 Message: 55901

Hello to all:

A few months ago I noticed my TS-520 had a voltage on the cabinet. I saw a little sparking on the outer conductor when I was connecting a Coax line. At the time I did not have the cabinet grounded.

I thought the safety caps need changing and I finally got around to changing them this week. Unfortunately changing the safety caps did not resolve the issue.

I have done some voltage checks and find the following:

120vac on the cabinet with rig turned off. This drops to zero if I reverse the line plug at the wall receptacle.

60vac +/- with the rig turned on. It is the same regardless of of the line plug position. Flipping it only makes a few volts difference either way.

At this point I am not sure how to proceed and I am looking for direction..... I would be inclined to think about examining the transformer for a short but would like some input before going that way. What could be the possible source(s) of line voltage on the cabinet of a TS-520?

Thanks

Dan KI4AX

Hi Dan,

Sounds like, to me, either a compromised power transformer or a bad cap C11, 12, or 13.

Best luck, and don't jolt yourself!

Dan,

Those "safety" (actually power line filter/interference suppression caps) caps you changed out form a capacitive voltage divider from both sides of the AC line to the chassis. That puts approximately 1/2 of the line voltage (60VAC), at very low current, on the ungrounded chassis. If the chassis were properly grounded using the ground stud on the rear of the chassis you would not see a spark or feel a tingle (or worse...).

A better replacement for those ceramic caps are X, Y, or XY line safety capacitors. The "X" caps are designed to go across the AC line and "Y" caps are designed to go from AC line to ground or chassis. Combination "X/Y" caps can be used in either location. Regardless, ground the chassis.

Here is just one link that explains the situation you have and why you want to use real line safety caps:
http://www.justradios.com/safetytips.html

Sent to Terry 11/15/16

Good morning Terry,

This morning I adjusted both the 9 volts and RF1 (3.5 volts) on the AF AVR board.

The 9 was close, at 8.89. Brought it to exactly 9

RF-1 voltage was low, at 2.9, so you advised me to bring it up to 3.4-3.5.

I brought RF-1 voltage to 3.5 and now S-meter is at zero with no antenna and receiver RF Gain control all the way up.

AND, now when I go into XMIT the ALC meter is dead on ZERO, and the mic gain control only needs to go to 3, rather than 7 to obtain full ALC/output indication!!

I kind of feel stupid on this one. I should have checked and set these voltages as a first step.

Live and learn.

The last two issues I will address down the line with this radio are-

1- align the Speech Processor

and

2- Align the Noise Blanker (does not work as well as the blanker on my TS520se of TS930s)

Shall I just go by the instructions in the service manual on these two items?

Again, Again, I say thank you for your help Terry. You surely are sharp on these radios!!!

73, Bruce N4JHY

On my TS-530S, I have also noticed that when I have resting IP set to 60 ma in USB and LSB (as directed by the operators manual and the service manual), resting IP is 70 ma in CW mode.

So after reading Terry's post about this, I decided to go back and readjust VR-4 and TC-1. Following the manuals, with mic gain=0, the meter in RF position and the RF meter sensitivity pot on the back of the rig turned to maximum, I adjusted V$-4 and TC-1. There is absolutely no meter deflection in any mode. Therefore, the null is perfect. But I still get 70 ma in CW mode and 60 ma in USB and LSB mode.

Playing around with VR-4 and TC-1, there is absolutely no setting that gives me resting IP in CW mode that is equal to (or below) resting IP in USB and LSB mode.

I'm probably digging into this more deeply than necessary, but if anyone (especially Terry) has an idea why I can't get resting IP to be exactly the same in SSB and CW modes, I'd appreciate knowing.

I ALWAYS had more resting current on CW. I ran a TS520 for 40 years and that is just what you have. O n CW You ran Class C bias on the old classic Tube transmitters and had cathode keying to keep the final tubes cut off on key up. My radio is Ham Radio...CW is Real Radio 73, John...K8JD

Key is in the jack but open. Switch flipped to SEND.

With no key in jack and switch on SEND, idle goes to 130 ma. Why is that, just curious?

Turn the CAR Level Pot full CCW.

Try this test:

1 Remove the code key from the jack
2. Turn Mic gain and CAR pot full CCW
3. Place mode switch in USB and Flip to Send and set your operating bias to 50ma (because easier to see)
4. Place mode switch in CW and Flip to Send and intentionally adjust BM trimmer pot VR-4 for 70ma.
5. Go back to USB and Flip to Send. Do you see 50ma? Now you have 50ma resting plate current in SSB mode and 70ma resting plate current in CW mode. Why? Because BM Carrier Suppression is not properly nulled.
6. Go back to CW mode and Flip to Send and null the IP reading back down to 50ma. You will be close to proper carrier null, but better to do it by following Step 23 as RF millivolts across 50 ohm dummy load is more sensitive indicator than Plate current.

I can tell you I see a lot of radios where the USB/LSB carrier suppression hasnt been properly nulled or balanced as KW likes to call it.

So assuming that you have in fact properly nulled the USB/LSB Carrier then the reason for seeing two different levels of resting plate current between USB/LSB and CW is as follows.

You have two different paths for the grid block diodes that produce slightly different -C supply voltage levels due to slightly different load resistances used to ground the -C supply.

With code key in jack and press the code key in CW mode you ground the -C supply through a 100k resistor.

With no Key in Jack and you Flip to Send or use the Mic PTT to key the radio you ground -C supply thru RLT (RL-1 relay contact) turning on Q27 transistor switch to ground (turning it on hard).

Each method of grounding the -C supply produces slightly different -C voltage levels which ends up with slightly different voltages at VR2 wiper of bias pot and on to the FG line and to the Final Tube control grids.

KW is not changing the bias voltage to change the Class of Operation in CW mode. If that were the case would lower it toward cut-off and not make it higher away from Class AB1 on the load line.

Typically if you set the bias voltage for 60ma in USB mode with the Mic gain full CCW and then check the bias in CW mode with the CAR Level Pot full CCW and Flip to Send or key the Mic should see same 60ma. If you dont that is normally due to not having the Carrier nulled in USB mode.

We have spent way too much time on this. I simply wanted to say that very common to find the carrier suppression not fully nulled and not balanced and that affects the plate current you will see in CW mode with the CAR Level pot full CCW.

Step 23 tells you that the acceptance criteria is "less than -50dB below" what you see in CW mode at full load (100 watts) into 50 ohm dummy load (Step one of Step 23). Now what does that mean? At 100 watts you should see approx 71 rms rf volts on your scope or RF probe/VTVM. -50dB down = 71 x 0.003162 = 224mv rms or 636mv P-P. So when you are nulling the carrier and trying to get same null in LSB and USB you need to be at or below 224mv. That is usually easily attainable, but not always easy to get both LSB and USB at same voltage level mainly because have no way to balance the output levels of the TS530 LSB/USB carrier oscillators. Before you start Step 23 suggest you clean both VR-4 trimmer and TC-1 trimmer. Especially VR-4. After cleaning VR-4 apply drop of Fader lube or WD40 with artist brush or tooth pick and distribute on the carbon trace by exercising and do not blow it off with canned air.

I am moving on as wearing out my finger tips!

When are set to CW mode and you remove the key plug the jack is supposed to short and you are going into the CW transmit mode like you had the key down ! 170 mA Pllste current and 100 W going out ! If you have the VOX function on or have the Send switch on, you are going on the air ! My radio is Ham Radio...CW is Real Radio 73, John...K8JD

Okay, that explains why several of the steps in the service manual that
say to put the rig in CW mode and set mode=SEND don't mention closing
the key. Those steps assume that you don't even have a key connected
to the rig, in which case the rig will automatically "key itself" when
you put it in SEND mode.

Thanks for that info.

From: wagstw46@...
Topic: 55879 Message: 55917

That is correct.

Only time you install Code Key when aligning Hybrid is to check the CW side tone oscillator function and set its level and to test Semi Break in CW mode. All other tests and adjustments that require CW Send the radio is keyed by Flipping to Send.

No where in the Operators Instruction manual does it tell you to set the zero signal plate current by inserting a code key in the key jack and closing a Code Key. It tells you to place the rig in SSB mode and flip the Standby switch to SEND. If they want a code key in the key jack the Service Manual Conditions Column will tell you to plug a key in. This detail will be under the Procedure heading in the non-column format of the Hybrids prior to the 530/830 rigs.

In some of the manuals including the TS520 rig you have to look at the Initial Switch Settings Table to see that you need to set the radio in USB or LSB and turn the Mic gain pot full CCW. Then under Step 4.9 it tells you to flip the Standby switch to Send and set the plate current to 60ma. The reason you set the mic gain full CCW is because it is good practice as want nothing coming down mic line to the BM that would produce any output and affect the Ip reading. The related Service manual may refer you to the Instruction manual for how to make this adjustment.

Interesting how some owners dont read the manuals or blow past it or read and dont comprehend and/or just develop operating habits that are not directed by the Manuals.

If what the Manual directs doesnt make sense then this is the place to come for clarification or amplification. No shame in that and you may find more than one opinion. That is when we can have a sometimes spirited debate.

Back in the day very few Novice hams bought a brand new KW hybrid transceiver as their very first receiver/transmitter with never having operated any ham gear of the period. The manuals are written to a certain educational reading level and with the assumption that new owner has loaded a Pi-network transmitter. That is why sometimes it seems as if not enough meat on the bones.

Thanks Terry. Good explanation. I agree that the manuals don't say anything about inserting a code in the jack when doing an alignment.

To me, keeping a code key plugged in seemed just as natural as plugging the rig into A/C mains power. Who would ever run the rig without a key plugged in? (Lots of people, nowadays, I guess.) The alignment steps don't say "plug the rig into the outlet", either. Nor do the alignment steps also don't say "remove the mic". Instead, they say to turn the mic gain down when performing steps that require no audio input. Of course, there's not way to "turn down the key gain", so the needs to be unplugged during service.

Thank you again for your clear explanation.

Ken:

The replacements I used were the X/Y type and I used them to replace C38 and C40 (which were located between one of the 120v terminals and chassis and one of the 0v terminals and chassis at the bottom of the transformer).

I understand that the rig needs to be grounded as a safety precaution and to suppress stray RF, but I can't imagine that the Engineers would design a piece of gear with line voltage on the cabinet.

Are you saying that the 120vac (or the 60vac) on the cabinet is not dangerous? Are you saying that this is normal? I have owned the rig for 30+ years and do not recall ever having a hot chassis....

Thanks

I would remove my personal rigs from the operating position and move them to the bench for service and/or alignment and would never think to move my paddle and keyer to the service bench.

When I want to do any troubleshooting or testing or alignment on CW TX I reach into bench drawer and pull out my trusty old J-38 and plug it in. Brings back fond memories of porcelain dpdt antenna knife switches and lite bulb dummy loads!

Otherwise, no Code Key in the rear panel jack when servicing any customers KW Hybrid radio.

I have more than once gotten email from person who said rig wont load and I ask about key in jack and they respond with an "Oops".

Many different "standard" operating practices.

Dan,

Good that you used X/Y caps. They are rated for AC line service and designed to fail safely unlike the ceramic versions they replaced.

The use of those filter caps that form a voltage divider was common practice for many rigs besides Kenwood. Look at the schematics for the Yaesu FT-101, the Drake AC-4, and Hallicrafters equipment to name a few. The filter, consisting of those caps, was designed as a "system" with the expectation that the chassis would be grounded by the owner as specified in the owner's manual in the installation section. The grounded chassis is a necessary part of the "system" and the filter doesn't work as designed/specified if it is not grounded. One of the side effects of not grounding the chassis is voltage, at low current, on the chassis.

You saw a spark when you connected the grounded coax cable to the *ungrounded* chassis. Once the coax was connected the chassis voltage was removed but the coax shield is not a proper ground. Yes, under the right conditions the *ungrounded* chassis could be dangerous to you or to equipment you connect to the rig. If the chassis is grounded there is no danger. In the installation section of my TS-520 manual it states that to prevent electric shock, TVI, and BCI select a good, effective ground and connect it to the ground terminal.

I hope this answers your question(s).

Ken

Topic: 55699 Message: 55923

I have replaced the cathode resistors so the total now reads 5-ohms dead-on. The PSUs are all working fine and the EHT does not sag on-load. I have swapped out the PA tubes for NOS 6146Ws (late manufacture so same as 6146Bs). The only problem now is that I get only 50 watts out on CW for 220 mA plate current, tuned for maximum on the dummy load power meter. I have yet to neutralize the final but it should be OK on 7 MHz. Voltages are as follows:

Receive (heaters ON)
Vg1 = -102 V
Vg2 = +260 V

TX (CW no drive)
Vg1 = -103 V
Vg2 = +260 V

TX (CW 7.1 MHz)
Ia = 60 mA quiescent
Ia = 220 mA max
pOut = 50 W
Vg2 = +245 V

TX (LSB 7.1 MHz)
Vg2 quiescent = 260 V
Vg2 sustained speech = +245 V minimum

The Vg2 screen voltages are about 20 V up on what the manual says. Have I got a sticking relay somewhere? All thoughts gratefully received.

Best wishes to all -
Peter G3PIJ

Ken:

Your response is spot on. All the manuals clearly state to connect a good earth ground to the rear panel ground stud for the reasons you state.

I am fortunate to have a lawn sprinkling well pipe that my shack ground buss behind the operating position is bonded to via a relatively short cable run and a large copper clamp with serrated teeth that bites into the pipe just before it exits the concrete foundation pipe sleeve.

Challenge today for many homes on well or city water is they have an entirely plastic pipe supply and distribution system. Other choice for them would be driven ground, but those arent always effective or long lived. Of course 2nd floor shacks can also be a challenge.

I see a number of KW hybrids that the owners have installed 3 wire line cords and I get asked about it from time to time. Lots of different opinions on this mod. It of course relies on the safety neutral conductor (green wire in the cord and bare wire in the romex) to tie the rigs chassis and cabinet to the utility neutral in the breaker or fuse load center. One problem with this can be that the bare safety wire may not be a continuous run back to the neutral in the load center.

So if going to rely on that 3rd wire in lieu of a safety earth ground then might open up 120vac receptacle at the operating position and ring that wire out back to the load center and maybe even measure its resistance. Especially true if older home.

Thanks
Terry K9TW

I can't resist commenting on the statement in Kenwood manuals that the rear panel stud should be connected to a good earth ground.

For electrical safety purposes, connecting the rear panel stud to an earth ground is USELESS unless the earth ground is also bonded to the service entrance (load center).

The ultimate authority on electrical wiring safety, Mike Holt (mikeholt.com), probably explains it best: "Those little electrons are very smart. They know to always return to their source."

So if you connect the rear panel stud to an "earth ground" that is not bonded to the service entrance ground, you're going to have a considerable amount of resistance between your station's earth ground and the service entrance ground, since the path between the two "grounds" will consist of soil. For most residences, you'd be lucky to have earth ground resistance as low as 25 ohms -- so a isolated earth ground is almost useless (and a code violation according to the NEC.)

If you have a station ground rod, it MUST be bonded with copper wire to all other earth grounds, including the service entrance ground. In that way, the station earth ground will then provide a low resistance path to the service entrance.

Good explanations here on W8JI's pages, although the focus is mainly on lightning protection. But if you conform to the principles in W8JI's pages, you'll be conforming to the rules for both electrical power safety and lightning safety.
http://www.w8ji.com/house_ground_layouts.htm

Some excellent videos by Mike Holt that explain electrical power system bonding here. Fun to watch and very informative:

Subject: Re: [TS-520_820_530_830] Re: TS-530SP Questions

That is correct.
Only time you install Code Key when aligning Hybrid is to check the CW side tone oscillator function and set its level and to test Semi Break in CW mode. All other tests and adjustments that require CW Send the radio is keyed by Flipping to Send.
No where in the Operators Instruction manual does it tell you to set the zero signal plate current by inserting a code key in the key jack and closing a Code Key. It tells you to place the rig in SSB mode and flip the Standby switch to SEND. If they want a code key in the key jack the Service Manual Conditions Column will tell you to plug a key in. This detail will be under the Procedure heading in the non-column format of the Hybrids prior to the 530/830 rigs.
In some of the manuals including the TS520 rig you have to look at the Initial Switch Settings Table to see that you need to set the radio in USB or LSB and turn the Mic gain pot full CCW. Then under Step 4.9 it tells you to flip the Standby switch to Send and set the plate current to 60ma. The reason you set the mic gain full CCW is because it is good practice as want nothing coming down mic line to the BM that would produce any output and affect the Ip reading. The related Service manual may refer you to the Instruction manual for how to make this adjustment.
Interesting how some owners dont read the manuals or blow past it or read and dont comprehend and/or just develop operating habits that are not directed by the Manuals.
If what the Manual directs doesnt make sense then this is the place to come for clarification or amplification. No shame in that and you may find more than one opinion. That is when we can have a sometimes spirited debate.
Back in the day very few Novice hams bought a brand new KW hybrid transceiver as their very first receiver/transmitter with never having operated any ham gear of the period. The manuals are written to a certain educational reading level and with the assumption that new owner has loaded a Pi-network transmitter. That is why sometimes it seems as if not enough meat on the bones.

From: n6oil@...
Topic: 55928 Message: 55928

Ok I know this is a sore subject but maybe one of the gurus can help me on this.

My TS-820S always has had display issues and seems to have a common pattern.

Here is the breakdown. x indicates missing digit.

Band Switch Setting: Display Readout: Dial Readout:

29.5 29.x81.7 29.000 =0.0
29.5 29.883.4 29.100
29.5 20.880 29.500 top of dial

29 29.882.5 29.000 = 0.0
29 29.8x0.0 29.100
29 29.xx0.0 29.500 top of dial

28.5 28.x82.3 28.500 =0.0
28.5 29.x81.1 29.000 top of dial

28 28.x82.6 28.000 =0.0
28 28.xx0.0 28.100
28 28.081.0 28.500 top of dial

21 9.x80.0 across the whole band

14 14.x82.3 14.000 = 0.0
14 14.x80.0 14.500 top of dial

7 7.x82.3 7.000 = 0.0
7 7.x99.0 7.500 top of dial

You get the picture.

I have a spare DG-1 and it's x.xx0.x from 160 to 15m and x.xxx8.x on 10m.

So question is what board should I try fixing first? The first board look as if it has been under the gun a few times, the spare looks like it's never been touched.

Thanks everyone.

Rory

Update: I swapped out the just the counter board and everything works fine except 15m, any ideas?

I wasnt promoting a 8ft or 10ft copper clad driven ground rod as the "earth" connection.

I also neglected to mention that I have a 240vac load center in my shack and I have the well water ground lead bonded to the neutral bar in the Square D panel. That panel is fed from my 200amp house service panel which of course has neutral coming via the underground service entrance cable that is crimp connected to the utility neutral at the top of the pole which also includes a bare copper ground down lead that is wound up underneath the butt of the pole.

Utility multi-point grounding is standard practice here, but doenst mean cant experience "neutral shift" due to bad crimp connection and appliances wont like that.

Peter:

Do you get approx 50 watts out on all bands or just 40 meters?

Do you have another 12BY7A Driver tube to try?

Do you have a means to measure the 7mhz RF drive at DRV?

DRV can be measured at the small set of plates solder lug on VC-3 air variable nearest the PA cage. Should be greater than 50rms rf volts or 140 P-P rf volts if using O-scope.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <peter@...> wrote :

I have replaced the cathode resistors so the total now reads 5-ohms dead-on. The PSUs are all working fine and the EHT does not sag on-load. I have swapped out the PA tubes for NOS 6146Ws (late manufacture so same as 6146Bs). The only problem now is that I get only 50 watts out on CW for 220 mA plate current, tuned for maximum on the dummy load power meter. I have yet to neutralize the final but it should be OK on 7 MHz. Voltages are as follows:

Receive (heaters ON)
Vg1 = -102 V
Vg2 = +260 V

TX (CW no drive)
Vg1 = -103 V
Vg2 = +260 V

TX (CW 7.1 MHz)
Ia = 60 mA quiescent
Ia = 220 mA max
pOut = 50 W
Vg2 = +245 V

TX (LSB 7.1 MHz)
Vg2 quiescent = 260 V
Vg2 sustained speech = +245 V minimum

The Vg2 screen voltages are about 20 V up on what the manual says. Have I got a sticking relay somewhere? All thoughts gratefully received.

Best wishes to all -
Peter G3PIJ

Terry -
ALC can be pegged on the right-hand stop of the meter on all bands. I think this test shows that the 12BY7 is OK. I'll put the 'scope on it tomorrow to make sure. I shall also neutralize the PA and see what power I get out on 28. I have another pair of NOS 6146Ws so I think I'll put those in just in case the existing pair are not as NOS as I thought.
I am hoping that the high voltage on the screen grids will not be causing excessive screen dissipation and secondary emission etc. I would have expected the resistors in the screen supply to have drifted high over time so the voltage should be lower than expected rather than higher, as I have measured.

For grounding, one might try reading/studying Tom Rauch, W8JI, webpage titled:

"House ground layouts"

http://w8ji.com/house_ground_layouts.htm

Another page on Tom's website is titled

"Ham Station Desk Radio Equipment Ground"

http://w8ji.com/rfi_rf_grounding.htm

I recommend members read/study Tom's pages on safety/lightning and RF grounding. I followed what Tom suggested and have never experienced any AC or RF issues.

The 100 ohm SG Stoppers are carbon comp and are hygroscopic, but seldom drift high enough to present much IR drop. About highest I have ever seen was around 125 ohms. They are not intended to provide any IR drop. They are parasitic suppressors.

Easy to measure or calculate the screen grid current and the dissipation. Methods include:

1. Lift SG lead off wire wrap post and insert ma meter. I wouldnt wreck a good wire wrap termination.
2. Lift lead off SG switch (unsolder it) and insert ma meter. Better than #1.
3. Measure the IR drop across each SG stopper resistor on the foil side of the Final board. Then measure the resistance and calculate the SG current for each tube. Here is typical example:

Front tube IR drop = 1.20vdc
Front tube SG resistor = 111.5 ohms
Front tube SG current = 1.20/111.5 = 10.76ma
Front tube SG voltage 225vdc
Front tube SG dissipation = 225 x 0.01076 = 2.42 watts
Max SG dissipation from RCA 6146B tube data sheet = 3 watts

Recognize that the tubes are in parallel with a single bias adjustment pot so they will not share the total plate current equally and the SG current wont split precisely in half. So need to do same measurements and calcs for the Back tube.

In this example IR drop was 1.21 vdc and resistor was 97.5 ohms making SG current 12.31ma. 225 x .01231 = 2.77 watts.

So in this example neither tube is exceeding the maximum SG dissipation rating of 3 watts.

I agree that 245vdc is a bit on high side.

As you note the Final tubes may simply be low on cathode emission. Driver tube is not likely the problem. If get same low RF output results with different Finals then might want to look at the Plate block and Plate RF bypass caps. I always replace both. The RF bypass body is often cracked. Plate block must be a Class 1 Temp Coefficient cap.

I'm sorry I'm taking so long in my reply...but I just obtained the new filter caps and installed them this afternoon.
Unfortunately, there is no change in my reduced output nor in my voltage measurements on the Rectifier board. As an example, on the "800" output pole going to the HV board, to the finals and to the filter capacitors, what I would expect to be in the neighborhood of 800v measures only about 625v DC. (exact same measurements with both the old and the new filter caps).
I disconnected the HV board connection and the connection to the finals, leaving only the filter capacitors, and the voltage measurement at the "800" pole went down even further...to 490v DC!
Going to the input pole to this circuit...the "AC800" pole...I measure only 360v AC between this pole and the "0" terminal of the transformer. Disconnecting everything from the transformer, the no-load measurement between the "0" terminal and the "800V" terminal of the transformer is still only 350 to 360v AC.
I would assume this transformer reading is not normal, but the schematic does not show any expected voltages in this entire Rectifier board area.
Any ideas or suggestions???

Thanks for all the informative replies. I already have my shack grounds bonded together. When I built my shack I tried to make sure everything was grounded and grounds were connected together. And, I used silver solder for the ground rod connections as opposed to a clamp.

I guess from now on I need to pay attention and make sure I get the ground connected BEFORE I plug the rig in.

Seems to me, though, that if there was SUPPOSED to be 120vac on the cabinet Kenwood would have put a bigger better CAUTION message in the Owner's Manual. You know something like "Caution - shock hazard." But, of course this is only my OPINION.

I just guess I am very lucky that I have not been injured. In all the 30+ years I have owned and operated this rig I never realized that there was 120vac on the cabinet.

Thanks again....

Dan,

My first commercial transmitter that I got as a novice, an Eico 720 from 1958, used four caps and two inductors to filter the AC line. The caps are wired exactly the same as in the TS-520. The Eico manual's first step for operating the transmitter is to connect a good ground. It was "standard" practice and followed by many manufacturers in the industry.

The more serious issue is that these line filter components are placed by most manufacturers BEFORE the line fuse for the equipment. That means if a line filter cap or inductor shorts to ground or across the line the only safe guard is the 15A or 20A circuit breaker or fuse for that circuit. Since most of the equipment has 18 gauge or 16 gauge line cord there is a possibility that the line cord can heat up and catch fire before melting and breaking the circuit. When I repair equipment I rewire the filter components so they come AFTER the equipment fuse so that any line filter component failure will not rely on the substantially larger house circuit breaker/fuse.

Another note, check that the "hot" side of the AC line is connected to the tip of the chassis fuse holder and not the terminal nearest the chassis. This is sometimes not the case. The AC line must be connected to the farthest terminal and the equipment is connected to the terminal nearest the chassis. This is a safety issue to prevent you from possibly contacting the hot side of the AC line while removing the fuse. Putting the hot side of the line on the farthest terminal ensures that the fuse will not have any voltage on it while being removed.

340 to 350vac unloaded is normal.The "800ac" on the schematic is a label and not a transformer secondary voltage.

It is a voltage doubler. Each cap charges to the peak and the two add. 340 x 2.82 = 960vdc.

Did you check the 4 silicon rectifiers?

The reading of 360 volts RMS AC is correct. The marking of 800 on the schematic is the final filtered DC output of the circuit. The circuit is a voltage doubler. So the output of the filtered DC is approximately 2.8 times the RMS or about 1000 volts (no load, falling to about 800+ at load). Since you replaced the filter caps, you should check D1,D2,D3 and D4 rectifiers. I think you may find one or more open or worse, shorted.

To check if its a loading issue, remove the final tubes and measure the HV DC. Be sure your volt meter can read over 1000V dc. (Had to throw the safety thing in there, I'm sure you're very careful around HV).

Terry -

Results for 7 MHz CW as follows:

Front 6146W
Rg2 = 104.5 ohms
Voltage drop = 0.70 V
Ig2 = 0.7/104.5 = 6.7 mA
Vg2 = 245 V
Pg2 = 1.64 W

Rear 6146W
Rg2 = 105.5 ohms
Voltage drop = 0.93 V
Ig2 = 0.0.93/105.5 = 8.8 mA
Vg2 = 245 V
Pg2 = 2.16 W

The real bonus is that I'm now getting 90 watts out into a 50-ohm dummy load for 240 mA plate current. Could this be long-unused tubes 'burning in'? Also, I don't trust the power meter better than +/- 5 percent or so. Maybe I'll put in different combinations of my five 'NOS' 6146Ws until I achieve screen currents that are more equal (give or take the odd significant figure here or there in the calculations). Then they need neutralizing.

Many thanks for your measuring technique.

Well...I replaced all 4 diodes and all 4 resistors in the 800v circuit and absolutely no change in my readings...still only 621v DC at the 800 post. I removed both finals and still have the 621v DC at that post.
The voltage doubler is doing only a 178% increase (348v to 621v) rather than the "advertised" 280% factor.
As I mentioned in an earlier post, I disconnected EVERYTHING from the 800v post with the exception of the filter caps, thus eliminating any potential load in other circuits from dragging the voltage down...still got my 621v DC.

The only components in the doubler circuit that have NOT been replaced are the .01 ceramic caps and the 470k resistors across the two filter caps. I replaced only the filter caps. Seems like that's all that's left.

Terry "RUE",

Did you check the HEATER switch to ensure it is turned "ON" and/or the rear panel SG switch which should also be in the "ON" position??

If the HEATER switch is OFF then TX tune up will not work regardless of the Mode switch setting.

If the SG switch is set in the OFF position by accident when handling/moving the 520 then TX will have zero IP indication in TUNE/CW/USB and LSB modes, no 60ma idling current, no dip in IP in any mode, and no RF output. However, if the SG switch IS in the OFF position you should still have TUNE mode DRIVE control peak ALC indication but that's all in TX.

If the above switches are in the ON position but you still have zero IP indication in any mode, check the final tube cathode resistors. If they are burnt open then there will be zero current flow in any mode.

Also check to ensure the driver tube and both final tube filaments are lite. The final tube filaments are wired in "series". If one final tube filament burns open then both final tube filaments will be dark, not lite.

Peter:

Very common for the Cathode current and the SG current not to divide precisely in half with the paralleled S2001A or 6146B tubes. Not something average person would think of or be concerned about. Would need seperate bias adjust pots for each tube to get them to share the load precisely. I actually had a rig here once where the owner had done just that. Really not necessary. I just recommend sticking with same brand and not installing one 6146 and one 6146B which I have seen more than once. 6146 has 25 watts plate dissipation.

I do buy matched pairs of NOS JAN ECG/Philips 6146W from RF Parts even though not needed for parallel config. I do that because they do energize them and test and run transconductance on them. If you dont buy matched pairs from them they simply reach in to a carton lot and pull two tubes out randomly and send to you.

With the matched pairs they are at least energized one more time since they were gettered at the factory many years ago. It is my hope that this energizing on RF parts bench might cull out any weak sisters. I understand they arent seeing same DC or RF drive operating conditions on their bench that they see in actual KW hybrid service. Might be flawed logic or wishful thinking on my part, but makes me feel better for very little additional money and never had one arc over, be gassy, or low emission.

Where did you buy the new HV caps from? Did you keep the two old caps? Can you ID the good one of the two old ones you replaced?

Could try paralleling good old one across each of the two new caps one at a time using alligator or mini-grabber leads. Would have to be very careful doing this.

First could measure the voltage across each of the two new caps to see if splitting equally. Have to do this very carefully. Should see close to 310vdc across each one.

It would be safer if you had an ESR meter and could ESR the two new caps with the line cord unplugged from 120vac recept and the caps fully discharged.

Well...I replaced all 4 diodes and all 4 resistors in the 800v circuit and absolutely no change in my readings...still only 621v DC at the 800 post. I removed both finals and still have the 621v DC at that post.
The voltage doubler is doing only a 178% increase (348v to 621v) rather than the "advertised" 280% factor.
As I mentioned in an earlier post, I disconnected EVERYTHING from the 800v post with the exception of the filter caps, thus eliminating any potential load in other circuits from dragging the voltage down...still got my 621v DC.

The only components in the doubler circuit that have NOT been replaced are the .01 ceramic caps and the 470k resistors across the two filter caps. I replaced only the filter caps. Seems like that's all that's left.

To be clear so I understand, when you state "800 post" that is the terminal on the rectifier board near D4, not the transformer connection at AC800 correct?
If the answer is "yes" then unless something is loading the transformer down heavily, and you would see that in components getting hot and the transformer sounding loaded (groaning), it means the ac source feeding the rectifier board is the problem. If the transformer is not getting hot, it most likely is not shorted turns. Please check that you have the primary voltage switch (on the back of the set) set to 120 volts?

That's correct, Tim...the post near D4...I would expect something close to 800v DC here, but get only about 621v AC.
The transformer input switch is indeed set to 120 and I have measured the input voltage to the transformer and find it to be 123v AC.
No groaning or heating of the transformer components observed.
Other forum participants indicate that the AC voltage at AC800 should be expected in the 350v AC range, so I would conclude that the transformer is operating in the normal range.

"ESR" - "Equivalent Series Resistance"

The "IDEAL" capacitor (or inductor) ("pure" capacitance or inductance) doesn't exist. But you can sort-of pretend to have such a critter if you posit a resistance in series with the reactive component (cap or coil).

When you're dealing with reactive components (caps and coils) you have to allow for their imperfections. An ESR meter will tell you if your components are aging or failing by measuring the amount of equivalent resistance (AT A GIVEN FREQUENCY!!) the reactive component requires to match the behaviour of a "perfect" component in that circuit at that frequency.

Aging or damaged reactive components (caps with failing dielectrics or small internal shorts, or coils with weak or missing insulation between turns, and so on) will show increasingly high ESR measurements.

ESR is just one more way to check on these kinds of parts. Henry or Farad ratings aren't all that you need to be aware of.

Remember that ESR is frequency-dependent, and some new parts which are totally unsuited for one circuit (i.e. at HF or VHF frequencies) might be perfectly fine for use at audio frequencies (i.e. 50 or 60 Hz power supply frequencies).

Components which have aged and gained significant ESR over time are suspect at all frequencies. New versus old is also a criterion in figuring out if something needs replacing or if it's still within tolerance.

"If It Ain't Broke, DON'T FIX IT." is a good maxim to obey when dealing with these radios.

I thought you had 475vdc on the old caps and not 310vdc? Now are you saying you had 620vdc before?

If you had 450 to 475vdc then you lost one of the old caps which is very common failure. If you had 620vdc not likely either old caps is bad. Unusual for one of these caps to fail in this manner. Usually the capacitance value doesnt change much over the life. Usually have swollen and cracked rupture vents and an open or a short.

Again, if you had 475vdc that means you lost one of the two original HV caps. Usual failure is to go open, but they can short. When they short can also puke out electrolyte and make a mess.

Can do a gross check on the two old ones you removed with ohm meter function on your VOM or DMM. If using an analog meter set to Rx10k range.

Remove the bleeder and rf bypass cap. Temporarily short the two terminals. Connect ohmmeter black lead to negative terminal on cap and connect red lead to positive terminal on cap meter will go to zero and then slowly climb to near infinity if cap is good.

Using a DMM you will see OL at first and the analog bar graph will go up scale quickly and the digital display will read something on order of 800k to 900k ohms.

If the cap is open the DMM will read something on order of 30 to 40 meg. The analog meter will probably just stay at infinity.

So first test is to see if the 621vdc is dividing equally across each of the two new caps. If it is then nothing wrong with either cap. If voltage is not dividing equally then temporarily bridge each of the new caps with the good old one that you removed. It is possible that one of the two new caps is bad. Dont need rf bypass cap or bleeder resistor back on the old cap for this temporary test.

DO NOT try to hold in hand and touch the old cap terminals to the installed cap terminals. Safer to attach bridging cap with rig down powered and use alligator or mini-grabber leads and get self in clear and then re-power.

Mike:

OK I thought he said no change after replacing the filter caps and still has 620vdc and not 475vdc ????

If he is saying he had 475 before and has 475 now you are probably correct they are now in parallel. As you know 475 before replacement clearly indicates a cap failure and he was given correct counsel to replace both. However, I dont know then where the 620vdc comes in.

I thought he was measuring it on the 800 wire wrap post on the HV Rect board and/or on the 800 wire wrap post on the HV unit board? If so, then cant be caps in parallel resulting in 620vdc at top of the RF plate choke.

It is clear this old man is confused and needs to let the others work this out!

So frustrating to not be able to see this and could find and fix in matter of minutes. Maybe the next Yahoo forum member generation will have better than Skype or Face Time capability.

Terry,

I preface the following with, I mean no disrespect towards anyone.

Dennis initially posted:

"/With the rig's meter in HV, I have only 450 v instead of the usual 800v./"

I suggested, based on Dennis's comments, that his problem appeared to be a filed HV filter capacitor.

After a few days Dennis then posted:

"...../I just obtained the new filter caps and installed them this afternoon.///_/

Unfortunately, there is no change in my reduced output nor in my voltage measurements on the Rectifier board./___/

As an example, on the "800" output pole going to the HV board, to the finals and to the filter capacitors, what I would expect to be in the neighborhood of 800v measures only about 625v DC. (exact same measurements with both the old and the new filter caps)./"

Where did the "625V DC" come from when Dennis's initial measurement was '+475VDC" and even after replacing the HV filter caps and D1 thru D4 and the 4 equalizing resistors, the voltage did not change????

Dennis then said:

"/I disconnected the HV board connection and the connection to the finals, leaving only the filter capacitors, and the voltage measurement at the "800" pole went down even further...to 490v DC!"

/A new lower DC voltage.

Dennis then stated:

/"Disconnecting everything from the transformer, the no-load measurement between the "0" terminal and the "800V" terminal of the transformer is still only 350 to 360v AC."/

I also wonder if Dennis may have reconnected the 0-400-800 transformer secondary taps to the Rectifier unit's AC800 pin "incorrectly", i.e., connected to the "400" tap????

Then Dennis provided another DC voltage:

/"Well...I replaced all 4 diodes and all 4 resistors in the 800v circuit and absolutely no change in my readings...still only 621v DC at the 800 post."/

I'm confused as to what the actual DC voltages Dennis measured are???? Dennis provided 3 different DC voltages (+475VDC, +490VDC, and +621VDC) at the Rectifier Unit's "800" terminal and none of them make sense especially after Dennis replaced the old capacitors with new caps and hopefully connected the HV caps in "series" as they should be instead of connecting them in "parallel" which is wrong. Also, hopefully Dennis connected the transformer's "800" tab to the Rectifier Unit's "AC800" terminal instead of the transformer's "400" tab to the Rectifier Unit's "AC800" terminal????

I'll ignore the comments about the confused old man....although I'd be the first to admit that I am old and I am confused...and this depth of electronics discussion is way beyond my pay scale.

I'm actually talking about 2 or 3 different voltage measurements...but I obviously didn't make it clear enough about those differences.

The 621v DC measurement is from the "800" post on the rectifier board...right next to D4...with everything downstream from this connection (filter caps, HV board, etc.) normally connected.

When I DISCONNECTED the HV card and the wire up to the finals, leaving only the filter caps connected to this "800" post, the measurement dropped even further...down to 490v DC.

The 450v DC measurement had nothing to do with this circuit! That was the reading on the Kenwood's meter in HV mode while transmitting into my dummy load...this should normally be in the 800v DC range.

So now that my dementia has been explained away, I believe I have found the culprit...but I haven't tested it out yet.

Somebody, in this rig's past life, has added two 4.6 ohm resistors in series between the infamous "800" post on the rectifier board and the connection to the + side of the first filter cap...I assume for some sort of voltage stabilizer or protection (???). It's not on the schematic. I noticed this a few days ago, but forgot about them being part of that voltage doubler circuit. This morning I tested those two resistors and BOTH are open...so there is no continuity between the "800" post and the filter caps!!

For testing purposes, I'll connect the filter caps directly to "800" and test the voltage. What's your opinion about putting the 9 ohms back into that circuit?

Dennis

With no heating of components, transformer output correct, new diodes, primary switch is correct, I agree, this is indeed strange, but also agree that a closer examination of the wiring of the new caps is in order.

But I am confused here. I thought that he read 630V at the 800 terminal of the rectifier board. I cant think of a cap or diode failure that would produce that voltage. If it is 475v, then a miss-wiring of the new caps is definitely possible, assuming ofcourse that the new diodes are ok and installed correctly.

Chances are that if the caps are in parallel, he will read the same voltage across each one, and that could be a misleading bit of data.

Recheck the wiring of the capacitors.

Tim

Dennis:

I was NOT calling you a confused old man. I was referring to ME.

It sounds like the two series connected resistors are there to limit fault current during tube arc over. It depends on where they are at in the circuit. Hopefully, they are correct type resistors for that application and not intended as sacrificial elements. Ohmite Type OY make good pulse current resistor that will serve in glitch resistor application. In your Hybrid dont want to design a "glitch resistor" in the anode supply to act as a fuse.

Never want the Plate voltage to open under a fault while the SG voltage remains on the tubes. Good way to destroy the tubes. So never install a fuse the anode supply to the RF plate choke.

If you have an arc over will have 900vdc limited by 5 ohm cathode resistance plus the equivalent secondary resistance of the HV supply. If only 5 ohms then 900/5 = 180amps which explains why the cathode resistors will leave with a bang. If have an ESR of 10 ohms then 900/15= 60 amps and would still likely lose the cathode resistors. Adding 10 ohms "glitch resistor" then 900/25= 36 amps. Cathode resistors might hang in and allow the 6A fast blow fuse to open. Assumes that proper fuse is in the holder and not an automotive fuse. I see all kinds of fuses with MDL time delays quite common.

If you dont know what the resistors are for would be advised to remove them.

So once again I was not calling you an old man.

Dennis

If those resistor are carbon comp and have drifted high up in to the meg ohm region that may be your problem.

Again it depends on where they have been installed in the 900vdc anode supply and where you are applying your volt meter.

The resistors may have normal 900vdc on one side (feed) and then when you apply your 10 or 11 meg meter to the load side or down stream side of them you read 620vdc. This is because the 900vdc supply has been converted to a high Z power supply and cant support any current. When you touch your 10/11 meg meter probe causes current to flow and a high IR drop across the two 4.6 ohm resistors. In this case approx 320vdc being dropped across them.

I would jumper them out and see if you can carefully measure 950 vdc at the top of the RF Plate choke in the PA cage.

If so, it is possible that there was nothing wrong with your HV caps, but good idea to change them out based on their age under the preventive maintenance umbrella. Maybe you had a Final tube arc over event which is anode to cathode and welding current for millisec and that may have hurt these resistors although carbon comp resistors can stand a very heavy overload for quite some time before damage or value change.

Please let us know what you find as have a lot of folks scratching our heads.

That is all from this Old Man! Sorry about that.

OK...thanks for the input, Terry, and sorry for the mis-interpretation (although I AM a confused old man)...

I connected the 800 post directly to the filter cap and everything works fine...Close to 1000v DC at the 800 post now instead of the previous 621v.

And the rig loads up at full power now into my dummy load!

The (open) resistors that I took out seem to be plain-vanilla 1/2 watt 4.6 ohm 5% carbon-film resistors. I'd probably replace them with something similar, but maybe 2 watt.

Dennis

The resistors were added as a "glitch" protection in the event there was a catastrophic failure of one of the final tubes or filter capacitors. It supposedly saves the transformer by first current limiting the huge surge current and supposedly opening up. Better than a fuse because of the inherent current limiting of the resistor. Looks like they worked for you, based on your original post.

Glad you found the issue. We were running out of failure modes to check for. (Darn those mods that people forget to mention.....;<)))

Hope it works for you, and YES I would replace the resistors. Transformers are a lot harder to find and replace.

Tim

I would never place a carbon comp "glitch" resistor in the anode lead of a tetrode.

If you do replace suggest you pull up the Ohmite OX/OYdata sheets. Need to use a pulse duty resistor for current limiting. You dont want any fuse action.

Go to WB4HFN website and see my mod to protect the panel meter. It is the weakest link.

It is usually NOT advisable to replace any of the resistors in the KW hybrids with a higher wattage, especially in the screen, cathode, or HV supply circuit...if those resistors keep blowing, there is something else wrong! I do however, replace the out of tolerance/spec resistors with carbon film or metal film versus standard carbon comp.
See this for some good info: https://xa.yimg.com/df/TS-520_820_530_830/Final+Unit+Cathode-Screen+grid+protection+mod..pdf?token=bKiHiSDpUjucMPQP919xQM8bPbSDrLFE65bAeQ4KaOZ94IufmnI0t3RADpNpXDKKNMAnpQOixx3fIIzdTaUZ487UuWPd0LeiIPgx9iZRwoR1xMjMvtL1Gg9WBgiwFuHMrAn_nFAEKLI44l9txNIeP0MDikN3u_ecBege&type=download

Hi Joe:

The resistors in question are a mod and not KW design config or KW factory installation.

The mod evolved from the Final tube arc over events and the the popping of cathode resistors. I previously promoted installation of these resistors, but havent installed any in the last year or two.

On the other hand I do install a 3 diode silicon rectifier string across the Cathode resistors in nearly 100% of all radios which pretty quickly limits the IR drop to approx 2vdc instead of 800vdc plus during an arc over event.

The meter circuit will see approx 1.75vdc at 350ma Ip (FSD) so 2vdc wont destroy the meter movement. The diodes do not effect the normal meter function or accuracy.

Since installing this mod in my personal Hybrids and most of the radios I service have not lost a Cathode resistor or a Panel meter and no reports of loss from any customer. Based on this experience I decided to no longer install current limiting glitch resistors so that the primary fuse would see more initial fault current and more likely act quickly to clear the fault assuming a proper 6A fast blow fuse is in the holder. It is a race to see if the fuse blows during initial fault current level and the time it takes for the diodes to switch and limit the fault current to 400ma (2vdc/5ohms = .40amps).

I cant tell you the number of customers who have emailed thanks that they no longer have to repeatedly replace popped cathode resistors. Of course most of them dont know how many times their 500ua meter movement has dodged a bullet. I have probably replaced 8 or 10 meters that if the initial fault didnt hurt it the Final tubes open cathode potential rise (well over 100vdc) got it when they placed meter in the IP position and tried to load again not realizing they had just incurred an arc over event that popped the Cathode resistors open.

Any way your counsel regards wattage ratings is good, but with respect to these resistors I would remove them or at least replace with type OY.

Thanks to EVERYBODY who has posted to this thread!! I have learned a lot, and have been able to solve my problem with the TS-820S.

I decided to replace the two "glitch protection" resistors between the "800" terminal on the rectifier board and the filter caps. They apparently did what they were supposed to do when I was mis-tuning the rig and caused the arc-over in the 6146(s)...protecting the filter caps and/or other components.

I have the rig all "buttoned up" and it seems to be working just as it did prior to my messing it up.

Thanks again!

Very unlikely that mis-tuning caused 6146 arc over.

More likely to cause Plate Load cap to arc over. Air variable arc overs are bad as can cause pitting and/or raised metal at the arc over point and very likely to have repeat arc overs at that spot. Hard to remove raised metal and restore factory smooth plate finish without changing the plate spacing.

The worse case "mis-tuning" scenario would be if you try to load with nothing on the SO-239. Weakest link in that kind of event is the Plate Load capacitor. It has BCB cap receiver plate spacing. It normally sees approx 71rms RF volts at 100 watts out. If you have a bad PL-259 solder connection or open anywhere in feedline or at antenna termination then impedance will be high and RF voltage will be high.

Actually you wont have a true open or infinite Z. You will have the combo of the two RF sniffer resistive dividers and the Xl of the safety choke in shunt across the Plate Load cap. So will be seeing something on the order of 10k ohm load and not infinity (approx 200 to 1 SWR).

I have measured the RF voltage across both the Plate Load cap and the Plate Tank cap with nothing on the SO-239 and will see approx 150rms rf volts across the Plate Load cap and the normal 550rms volts across the Plate Tank cap will increase to approx 720rms rf volts. The Plate Tank cap is wide spaced and it can typically handle the increase in RF voltage without arcing over. The voltages are held down a bit more on the TS820 and TS830 rigs due to the RF Negative Feedback circuit that will reduce the RF drive which then reduces the RF voltage across both caps.

At 100watts output the 6146 Final tubes see approx 1550 P-P RF volts (nominal 1600 volts). I DC Hipot all customers Final tubes. Any that cant hold off 2000vdc I recommend replacment and really prefer to see them hold off 2500vdc for adequate head room. Just tested a pair of new Taylor finals (chinese) and one broke down at 1600 volts and the other at 1800 volts. I dont know if because they use lower quality dielectric materials to support the various wire elements or the manufacturing environment is not as clean as the old RCA tube assembly lines?

DO NOT attempt to measure the RF voltage across either Pi Network air variable capacitor unless you have the proper test gear.

I am not sure what you describe as "mis-tuning". Long key down time and long off resonance key down time causes high plate current and chronic heating, but usually not acute failure of the Cathode resistors or the Final tubes. Very hard on the Driver tube that is running Class A at near max plate current. Your operating manual cautions about Driver tube damage.

If you did have a 6146 Final tube arc over I wouldnt be surprised if you have another. Sometimes can use the tube over again after an arc over and not experience another, but more common for a Final tube that has a propensity to arc over to see another event. If you do, I suggest you trash those Finals so not needlessly stressing the HV power supply components.

Terry

The PA tubes neutralized really smoothly - nice dip on the RF voltmeter across the dummy load as per the manual. I'm now getting 100 watts CW out on 80 metres dropping to 80 watts on 10 metres (both for 240 mA indicated cathode current which I suppose is around 225 mA plate current when the screen current is subtracted). These results are much what I've seen quoted elsewhere.

The final problem was a frequency jitter of around 100-200 Hz which I sorted by pushing the FIX button in and out about 20 times after a squirt of cleaner. CQ on 80 brought back a 5-9+ report of excellent signal quality and stability from 80 miles away. So job done and all sorted.

Many thanks for your comments and for the advice received from others on this site.

Peter:

The mini-PBs on the TS530/830 rigs are getting to be quite the problem.

Very hard to get any meaningful amount of contact cleaner into them via spraying. Mostly spray at them rather than into them. Sometimes can get some to wick down inside by placing rig on rear panel and with the front panel removed apply contact cleaner with artist brush around the actuating plunger area and hope gravity will work.

On most of the 830s I have been using a pin vise and series of small letter drills to open a small hole in rear corner fold of the metal housing that allows introduction of contact cleaner (similar to the holes on the rear panel mini-din switch bodies). Have to be extremely careful and control drill bit depth so that you dont contact the switch slide mechanism.

Cant use this method on the PC board mounted PBs.

Glad it came together for you. Have fun.

Patrick,
Welcome aboard, and good luck testing for your first "ticket." As discussed prior, the Kenwood hybrid series (520 through 830) are not capable of the frequency operations you mention(read the following). The early series, 520(S) through the 820(S) had as option, an external unit, a TV-506(for 6meters) and the TV-502(for 2 meters). They were not very popular, and are pretty much considered oddities or collector items. If you really want on to the stated specific bands, I would suggest a modern, new combo rig, capable of operating on the bands specified.
The early "hybrid" rigs are, in my opinion FUN, but with some caveats.
These rigs are not "plug-n-play" like modern units. It actually requires you to "tune up" the rig, versus merely "operate it." Please don't get me wrong here, modern rigs have their advantages....digital this...digital that..bell and whistle this, do have their places.
These older rigs are easier to work on/repair if needed. There is a vast quantity of knowledge and expertise here. You really need to do some further research as to what you want. The 520 series are fine rigs, and were basis for follow on rigs. Each have their pluses and minuses. A new person to the world of these fine hybrid rigs may feel intimidated at first...but with a bit of study of the operators/owners manual...you, like me, will get hooked. I still have, and operate my TS-820S.
This conversation, I know, will open a whole big can of opinions, but that's what we do here...to a point." Just remember the final decision is yours.
Good luck in your search, and remember, we're here to help you in possibly keeping these fine old rigs operating for many years to come. We don't know...but are these rigs possibly older than you? hihi

Hi Patrick,

You could not find a finer radio than a TS520 series transceiver to get started in ham radio on the HF bands.

As far as 6 and 2 meters. I prefer to have a second radio that is VHF only to work these bands.

Just think about it- if your radio develops trouble, and you send it off, you have nothing.

With separates, one for HF and the other for VHF etc, you still have a radio to use while the other is off being repaired.

Best luck, Bruce N4JHY Currently in study to get Extra ticket. Been a general almost 40 years!

Patrick,

Welcome to the world of Amateur Radio! I'm going to pass on to you a few comments and suggestions you may not have considered.

If you purchase one of the 3 models of the Kenwood TS-520 hybrid transceiver, make sure you receive the complete operator and service manuals with the radio. If the seller does not have either of the manuals then you can download them free from my website. Click on the following link.

http://w5rkl.com/manuals/

When the page comes up scroll down to the Kenwood listing and click on the appropriate operator and service manuals for the TS-520 model you have. I highly recommend before you plug your newly acquired Kenwood TS-520 hybrid transceiver into the wall outlet that you take the time to thoroughly read the operator's manual. If there are any sections you do not understand, do not ignore that section, come here and ask for help.

You can also purchase reproduced complete operator and service manuals for the various Kenwood hybrid transceivers from various online websites. Prices for the manuals vary depending on the website you choose.

A few additional items you should consider having:

1. 50 ohm dummy load and short coax jumper between your KW hybrid radio and the dummy load. An example of a 50 ohm dummy load is the MFJ-264, 1.5KW dry dummy load. The coax jumper can be purchased ready made from various online Amateur Radio websites or you can build your own by purchasing coax and PL-259s on various online websites.

2. A simple antenna for the band(s) you will be operating on. You can purchase ready made simple wire dipole antennas or build the antenna yourself using items found at local hardware stores. Coax cable will be required, RG8x is a good choice.

3. The FCC part 97 Rules that govern Amateur Radio in the U.S. and it's territories can be downloaded using the following link:

http://w5rkl.com/wp-content/uploads/2015/02/FCC-Part-97-Amateur-Radio-Rules-and-Regulations.pdf

4. ARRL Band Plan can be downloaded at the following link. Remember the ARRL does not control Amateur Radio operation in the U.S. and it's territories, only the FCC does.

http://w5rkl.com/wp-content/uploads/2015/02/Hambands_color.pdf

If your neighborhood has HOA antenna restrictions, then those rules will affect whether you can erect an Amateur Radio antenna or the type of Amateur Radio antenna you can erect. Consult your neighborhood HOA rules and the following ARRL links concerning PRB-1 and CC&R antenna restrictions:

http://www.arrl.org/prb-1

http://www.arrl.org/antenna-regulation-and-zoning

Again, welcome to the world of Amateur Radio and good luck with your license exam.

Hi Patrick, I have a TS520 I bought new over 40 years ago and upgraded to a TS440s to get on the WARC bands and now 60M. The 520 is old school with only 80, 40, 20, 15 and 10M. They are getting to an age where you need to do some maintenance now and then and if you have no background in Vacuum tube and high voltage work, Iwould go for something newer. If you take the Terchnician test you have to know morse to get on the HF bands below 10M or use fone on 10 Meters SSB and higher freq 6, 2M and hiigher FM bands. My radio is Ham Radio...CW is Real Radio 73, John...K8JD

Subject: [TS-520_820_530_830] First Rig Gear

  Hello everyone i'm Patrick, so new that I'm looking for gear while I study for my test. through email with wb7uqu I've been looking at the 520's, I like the looks of this rig, but another Ham had told me as well as wb7uqu that the 520's have no 2 Meter or 440 capability, So my question is how important is this, meaning from my research it seems a lot of folks are using these older rigs.

 Should I be looking at one of the later 70's Kenwoods. Needing a lot of help at this point.Thanks Patrick Rhéaume

55982. Hybrid Net Update (November 20, 2016)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-11-21 01:54:51 UTC

Topic: 55982 Message: 55982

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by me, WB0IQK. There
were 10 stations checking in under fair band conditions.

We had the following number of radios checking in.

3 running TS-520(x)
3 running TS-530(x)
1 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running TS-515
0 running 599 twins
0 running TS-900

He was running a TS-830S with an Drake L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
9 stations checking in good band
conditions. Even though we had good conditions,
the SS contest was going on and we had a bit of QRM being caused by that.

We had the following number of radios checking in.

2 running TS-520(x)
2 running TS-530(x)
1 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830S + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and

TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 □ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins
Nov. 2015 □ Oct 2016 Saturdays total 807 check-ins, Sunday total 628 check-ins

November 2016, Saturday net total = 53, Sunday total = 46 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

You can take every test element (license class) on the same day if you wish, for the one testing session fee. You take them in order, and the highest one you pass is the class license you will receive.

And there is still no Morse requirement.

I wish they would bring it back, to weed out a few of those who just commit all of the test questions to memory so they can be an Extra in one day (without knowing SQUAT about radio, electronics, or anything else).

Patrick,

Like you, I bought two Kenwood hybrids before getting my ticket, a 530SP, and an 830.

There is a feature Kenwood added beginning with the 530, and that is the WARC Bands. I find them a lot of fun, esp 12 and 17 mtrs. You wont get them on the 520, as was mentioned by another response to your request for info.

The 830 has a band pass tuning function not found on the 530, other wise, I find my two Kenwoods are quite similar in performance.

From a cosmetic standpoint, I must agree that the 520 is a bit more stylish.

Good luck,

Dave

Thanks Joe, well I'm 58 so the rig's are newer than me,lol. I know the end results are for me to be OK with, i know I can figure out/learn how to run this great machine. Maybe I should just ask how many folks will be on here with me.

I look at it like the common thread and as we all know thats a good thing to have when your the new folk.
So I'm pretty sure I'd be happy with running one of the Kenwoods knowing theres other out there as well.

The TS 520 is an excellent radio. I've been a ham since 84. Started out with a TS 520, been through many radios, and now I am back with theTS 520 as my primary radio. I'm a cw op and my operation time is very erratic. The only concern I have is making a contact. I don't chase DX or anything similar, just make contacts. It is an excellent radio for me.

IMO if I were recommending a radio. I would like to see the new ham get something newer -solid state- with an antenna tuner on board. This will allow the new ham to experience ham radio without the hassle of all the other distractions these older radios provide. The most important thing for the new comer is experience the hobby and have fun. Making a contact with ham radio on hf can sometimes be tuff due to conditions.
When I got my license in 84, I was 14. Regrettably, I did not keep the 520 long because of the tuning process and the constant tuning when band hopping. I now understand how simple it is but to a 14 year old, with no experience, or someone to elmer, it was very complicated and frustrating
Just my 2 cents.   Brian KB4MNG

Patrick,

The FCC has not reinstated Morse Code as an Amateur Radio license exam requirement.

A licensed Technician class operator is authorized to operate 80, 40, 15, and 10 meters HF using CW. The licensed Technician class operator is authorized to operate Phone (SSB) on 10 meters only between 28.3Mhz and 28.5Mhz.

The licensed Technician class operator is not authorized to operate AM or FM phone on any HF band.

The licensed Technician class operator is authorized to operate other modes on VHF and above. See FCC part 97 (part 97.301 and 97.305) for further details concerning the Technical class Amateur Radio license.

Hi Patrick,

Welcome to the best amateur radio equipment forum in the Yahoo Groups (in my opinion). My first Kenwood radio was a TS-520, bought years ago at Henry Radio in Anaheim, CA. It was the first "advanced" transceiver that I ever owned and I loved it. I upgraded from it to a TS-530S to be able to get on the WARC bands. Then I made the mistake of selling the perfect TS-530S (loaded with filters) to buy a more modern rig with bells and whistles. What a loss. I love the KW hybrids because I can work on them and keep them in perfect condition.

In any event I now own another TS-530S and have a separate radio for 2 and 6 meters. You will get much good advice on this forum, whatever your decision!

The Kenwood hybrids are excellent radios. I've had my TS-530S since 1982, when I bought it brand new. It has been a superb rig, with very few problems over the years. I have no plans to sell it, even though I also have a fancy new Icom IC-7300. I continue use my TS-530S every week.

Owning a rig from the early 1980's is a lot like owning a classic car from the early 1980's. It will serve you well and it's going to be lots of fun, but it's going to have problems here and there and it's going to need some maintenance. The problems won't be frequent, but there will be things that are going to go wrong. To fix the problems, you will often need hundreds of dollars of test equipment and specialized tools (actually more specialized than the tools for an older car). Many parts can still be obtained brand new, but sometimes new replacement parts will be impossible to get, so you will have to obtain used parts or rebuild some parts.

You will need a moderate to considerable amount of skill in electronics to troubleshoot the problems, or you'll need assistance from other hams, such as the help that you can get here on the forum. You'll also need to be able to unsolder and solder components.

If you are willing to spend the money to obtain the appropriate test equipment, if you enjoy a challenge and enjoy learning, you will probably get a great deal of satisfaction out of a Kenwood hybrid.

Or if you already have very good electronics skills and test equipment, including a very good DVM or VTVM, an oscilloscope and a frequency counter -- all calibrated to nearly NIST standards --- you'll probably be very happy with a Kenwood hybrid as your first rig. (True NIST-traceable calibration is not necessary, but test equipment whose calibration is unknown or that is way out of calibration is not good at all.)

However, if your initial goal is to just "get on the air", you will probably be better off with a newer, solid state rig. Used hybrids will be around for a very long time so if your interests head that way, you'll still be able to pick one up in the future.

Thanks everyone for your help along the way in talking about my first rig.
I'm 58, an old school, I love the look and construction of these KW's
So here is my line of thought being pretty much retired.

I'm studying for my Tech, someone told me if I get all the info
in my head for all three test that I can take them in order all at the same time and what ever my best score is that is the License I will be awarded..

So I'm not going to be doing anything until after the New Year, plenty of time to study and in the time being I can gather equipment.attend local club meetings and learn.

I also look at it that I'm new, if I'm limited on the 520 this lets me Master the Hardest part of Being a ham until I add something for the 2,6 Meter, For me I guess part of it all is the Nostalgia.

So Again many thanks, I do get and understand what folks are pointing out about these rigs and they don't want me to get disappointed in being a Ham with limits, Life is full of Limits so I master the ones I'm given only makes me stronger.
~Patrick

Hi Patrick, I am not sure what you mean "MC" ? do you mean MegaCycles? it's still MegaHertz.Do you mean "CW" mode and Morse Code? You don't need it to pass the test but a Tech class op can operate on 80-15 M on the lower freq General class portions on CW with Morse code so you need to Know it to operate there. No fone or digi modes allowed. My radio is Ham Radio...CW is Real Radio 73, John...K8JD

I think I may have an issue with the compression on my radio. When I transmit (SSB) without compression, I adjust the mic gain so that I get nearly full scale deflection on the ALC meter while speaking. The output power is about 100W. When I turn the compression on, I barely see any deflection of the compression meter, even when the knob is turned fully CW. I also notice that output power is about 50W with the compression turned on. Is there an issue with the radio, with my expectations or am I doing something wrong?

Hello Patrick

First off good luck on your test.

Now to the radio question. I personally don't like the “one and done” shack in a box. As previously stated if it develops a issue and requires service your dead in the water.

When I passed my technician test I was facing the same decision.

To answer your first question the VHF/UHF bands are the commonly used bands for local rag chews, local club nets, public event support and repeater operations. For these bands I went with a Kenwood TM-V71 which works very well as a base station and mobile, easy to use menu's and 3 separate power output levels easily selected from the front with one button. I have a separate radio that covers HF/6m with a built in antenna tuner and one button tuning which is great for DX chasing and contesting, covers bands the 520 doesn't and might be a better first choice HF radio until you figure out what type of HF operations you like.

That being said my favorite radio to sit down in front of and make casual contacts with is my 520S. Simple to operate, if there isn't a knob or button then it doesn't do it and no multilevel menus to remember. If it came down to having to dispose of one of my HF radios I more than likely let the new one go and would keep the 520S because it fits my HF operations just fine not being a serious contest operator and more a casual operator.

73 and happy hunting

Yesterday I sold my TS-520S. What a great radio. Last month I replaced the Original finals, the S2001's. I own two 830's, one Gold {Yes, full of filters...see K4eaa's page} and they sound far better on both ends than my modern gear. Actually selling off some of the newer HF stuff for it can't compete with the Kenwood Hybrids. I am also an audiophile. Much takes place converting a bunch of ones and zeros to analogue we can understand. They are trying to perfect it, but haven't yet. The new owner of the 520S was amazed how good it sounded. One of my rig has 500 memories. I think I use 6. Wonder if I can extract some to improve mine. 73's.

> awarded..

NOT quite true. You MUST PASS EACH ELEMENT IN ORDER. If you take the technician test and pass it, you can take the general test, and if you pass it you can take the extra test. If you pass the general but fail the tech test you WILL NOT get the general class license. (Nor the tech license either.)

The volunteer examiners (I am one) may allow you to take all three exams before scoring them, but you must pass them in order from lowest to highest class license.

My best advice is to LEARN and UNDERSTAND the material in the technician class, then worry about the general class test. Get on VHF or above for a little while, and do some listening down in the HF bands. (Or get a morse trainer and learn code, then start working some HF CW. The experience there will give you a really good grounding in operational procedures, as well as being a lot of fun.)

THE FOLLOWING IS SIMPLY MY OPINION. Disagree with it if you like, won't hurt my feelings a bit.

Going from "I don't know what anything is" to "I have the highest class of ham license and still don't know what anything is" in one sitting is NOT helping the hobby. Time was that someone who had an Extra class license was guaranteed to be a treasure-trove of information and help for all the other hams with whom (s)he had contact. If there was a strange problem with a rig, or somebody needed advice on an antenna or feed line, or couldn't quite seem to get the hang of some piece of gear or test equipment, the local Extra-class lincensee was the go-to for help.
,
Now, with the "new and improved" licensing system, we have Extras who don't even know what Ohm's law is, couldn't figure impedance of a coil or inductor, have NO single clue what resonance is or what a Pi filter does (or even why it's called a "Pi filter"), This is NOT an improvement.

Get the Kenwood radio. Learn about it while you study for your license and for your upgrades. These rigs are a full course in radio theory and electronics all in one box. Before long, if you use your noodle and do some learning, you'll be one of those Extras that can solve the tough ones, everyone knows to go to when things go sideways, and helps improve the hobby for everyone.

To me, that alone is worth the work and skull-sweat.

It is very common for the RF Procesor 445khz oscillator to be adjusted to 451khz which doesnt allow audio centered in the ceramic filters passband. The alignment instructions in the Service Manual are wrong.

It is best if you have good accurate Audio Gen and a means to measure RF voltage (O-scope or VTVM/DMM and RF probe) to perform the alignment. You need to inject low level 1khz audio into the mic line and adjust TC-4 for max RF voltage at TP-2. Should see approx 150mv to 175mv rms at TP-2. Additional step is to inject 300hz in mic line and adjust TC-4 for 6 db roll off or half the RF volts you had with 1khz input. May have to go back and forth couple of times.

Absent that if you have an accurate Frequency Counter you can just set the 455khz Oscillator on the IF board with TC-4 to around 453khz and call it good enough.

If no Freq Counter then listen to yourself on the Moni and adjust trimmer cap TC-4 for most amount of audio. Should be able to get peaks around 20 dB on the Comp Meter with Comp gain at 1200.

Terry K9TW

John, Morse Code, "Not" needed as part of the Technician class license. Nothing wrong with knowing/knowledge, But again "Not" part of the test was the point.

Being new I need to know what it is I have to study for the Test, thats all thats important at this time, I can learn other parts of being a Ham later, or if I want to get into that part.

Hi Patrick - I was in a very similar boat to you not all that long ago. My license is fairly recent and I went zero to General and then a few months later I did my Extra. I will never know all there is to know in this hobby - the amount to learn seems endless. You might first find out how much VHF activity there is in your area. Many new Technician hams are very excited to earn their ticket then come to find after the purchase of radios, the area they are in is mighty dead for VHF. That is not to say that purchase would be useless, there are many uses for VHF in that case including traveling, other repeaters, simplex and assisting in community radio efforts or emergency operations.

It is no surprise you are attracted to these Kenwood hybrids. This is a large and lively group here and there are thousands of these rigs out there in the wild. That is a testament to their engineering, design and owner loyalty to them. Bear in mind though that these rigs are a hybrid. They are at the point in time between tube rigs and solid state rigs. These rigs are mostly solid state but have tube finals, so you get the best (and sometimes worst) of both worlds with failure of resistors, capacitors and diodes and if you fry the tubes you will need to track those down to replace as well. Also, since these rigs have been around a while, it is difficult to find one un-molested by someone over time with varying mods and changes made by past owners over the year, with a frequent one being an 11M CB mod.

Depending on the hybrid, you might not have the WARC bands so determine if that is important the you. My 520s at least does not have WARC bands, so no 30, 17 or 12 or even 60M. You also will need to determine what it is you want to do with HF. Do you like contesting? If so, as I learned over the phone November Sweepstakes, the 520 series is perhaps not the best contesting rig. Any appreciable movement across the 80M band requires re-tuning and re-loading the finals which is often if you are searching and pouncing. Or perhaps you want a nice rag chew with a regular net or people you meet on the air. You won't find a better rig than these hybrids for that. My signal and sound reports are consistently excellent so much so I have people asking me what microphone I am using. So for my first HF SSB rig, I am absolutely in love with this rig and will never part with it. I love that there is a button, dial or switch for everything the radio can do and I am learning to use what is available to its maximum. It does not have all the features of a more modern rig, but I don't care. I am on the air, making contacts and enjoying simply being a ham.

Best of luck -
Dennis

My first rig as a ham radio operator was also at TS-520 (a mere 3 years ago!)-- it's an excellent radio, for sure. Though I do agree with you that a brand new ham might have some issues tuning each time they switch bands. It's my everyday HF radio, even though I now have a TS-590SG in the shack.

That said, the simpler interface on the Hybrids *really* helps new hams and would-be hams figure things out. I now regularly get brand new youth on the air (Field Day GOTA station, BSA Jamboree On The Air, etc.) and having a simple to understand interface (i.e. NO MENUS!!) is key to getting them on the air smoothly. I actually have found the Heathkit HW-100 and HW-101 are the perfect "user interface" for a new ham (once you sort out tuning and loading the plate, of course).

I highly recommend the 1980's radios for new hams, provided they are serviced etc. (watch out for old electrolytics). On the Kenwood side, the TS-430S, TS-440 are excellent with a minimal of confusion, and I'd also recommend the Icom IC-745, IC-735, Yaesu FT-747GX, and the like. I would AVOID confusing menu radios like the TS-590SG or something fancy like a K3 (bad rigs for a brand new ham, IMHO -- like giving your teenage son a brand new McLaren P1 Supercar to get to high school, hi hi) and also the IC-7000 or IC-706, or IC-718 -- those menus will turn hams off in no time -- and get them lost when they've somehow turned on IF shift and an extra filter or two, with second VFO and a shift offset and PL tone and can't figure out why they can't hear anything or transmit :-). Plus, as this new ham points out the confusion between VHF/UHF and FM and the HF with an all-band radio can really cause confusion.

I agree on an automated antenna tuner built into the rig (i.e. the TS-440) because it's fairly seamless. But I have seen more than one new ham get completely bolluxed on a computer controlled, automated external antenna tuner. There's nothing more frustrating than a new ham with his $2000 radio, $500 automated antenna tuner, computer-controlled iPad logging software and computer CAT connection... thrashing around for months trying to get on the air... who ended up not having his antenna connected properly due to simple coax issues!

Anyway, my two cents on this topic, not that anyone asked ;-)

A quick opinion. I think it is more fun to start at the bottom. Then as you learn, make improvements to your antennas, your radios, improve your station. If you try to start at the top, there is nowhere to grow.

I forgot to mention if you want to see where the 455khz oscillator is presently set or want to adjust its frequency using a Freq. Counter you need to connect the counter to TP-3. All other alignment steps you measure the AF voltage at TP-2.

I also mis-spoke. The voltage at TP-2 is AF (audio) and not RF so no RF probe is needed.

Again best method is to use stable and accurate Audio or Function Gen and inject 1khz into the mic line and make adjustments monitoring the AF voltage level at TP-2.

OK, so I have learn that the local guy did not have 2 520's for sale....But he has a Kenwood 241 Hand held, so this is going to be my 2 meter rig with a 520 for my anchor rig. As someone had mention I as well like starting from the bottom and working/learning my way up.

Starting with all the bells and whistle only adds confusion to an already confused head. I love the Old Kenwood look, whether I end up with a 520 or one of the other models, thats what I want in my shack.
Also as someone stated and as everyone knows, theres so much to lean I don't know that I have that many years at 58, and I like playing different games then what the majority of folks are doing.

So I do believe I will study to take all of my test at one time, or at least go for that and even if I have to take the next test I'll have a good lead on it.

Like most standard test I think theres question that really don't do much with operating a radio, and there could be better question about standard operational proceedures, but hey thats me.

So That is where I'm headed and what I'm going to do, I thank everyone for their knowledge and advice. I will be here for more of it.

No I meant into the front panel mic connector with ground lead from sig gen test lead on bottom left terminal and hot lead on bottom right terminal. I use a mic connector plug to make the connections using a mini-grabber to BNC test lead to make the connection from my Arbitrary Waveform Gen to the mic connector pins.

However, if you can couple audio from a speaker into the mic that is connected to the rig can probably make the adjustments. Would have to make sure that distance from sound level calibrator speaker is same at all times during the test and the sound pressure at 300 hz would have to be same at 1000 hz.

It would be better if the sound calibrator had a headphone jack output so you could go to Radio Shack and buy a patch cord. Need a very low level signal for initial adjustments and max of 10mv for final adjustments. I have done it with 1.0mv in lieu of 0.3mv that is called out and it works fine. My lowest level on my Gen is 1mv. I can connect step attenuators in the line to get down to 0.3mv, but a pain to do so I always align using 1.0mv.

There are some audio gen software available on the internet for laptop sound card. Might look into one of the free ones.

What will you be using to measure the AF levels at TP-2?

Again absent any test gear using the Moni can adjust 455khz osc trimmer TC-4 to get more audio into the pass band. Need to turn on the heaters and turn off the SG switch to have best audio quality in your headphones. You will be able to hear the improvement and see it on the Comp meter as should be able to get to approx 20dB on comp meter on voice peaks with Comp pot at 1200.

I have done a very large number of these and almost always end up with the 455khz oscillator set somewhere around 452.6 khz to 453.2 khz.

Terry K9TW

56007. Reviving attempt ... TS820S

Dear amigos ! I need help to be able to bring back to use a TS820S that was in long time storage. The reason for sending it to the storage was that it would not switch OK from transmit to receive, and also when transmitting it would suddenly stop the transmission...

Today I brought the radio to the workbench and applied very low AC voltage to it via a variable autotransformer. Also monitored the radio's input AC current...

The start up process went nicely after several hours.... maybe not enough, but seems sufficient to bring it back to life.

The problem is that when switching from receive to transmit and back it is intermittent... By switching the mode switch back and forth it starts receiving again....

The transmission quality on 40 meters is excellent... it tunes nicely into a 50 ohms dummy load, and switching the panel switch to monitor, the audio heard on the loudspeaker is very good.

I am wondering if I am able to pick up the 25 kHZ markers nicely and the transmission is good.... perhaps the problem has to do with the switching from receive to transmit and back... Maybe the relays are dirty ?

Another test running the finals at 200 milliamps plate current , from 50 milliamps idling current... produces very nice RF output that can be heard on another receiver with good quality...

Have yet to test the reception by connecting an antenna ... but I can hear the other radio transmitting at very low power while the dummy load is connected to the TS 820S

All possible problems that produce similar behavior will be important for me to learn more about this very old TS820S that is in a very nice state of conservation cosmetically...

BTW, the B plus goes nicely to 800 volts and there are no signs of anything overheating... but the FAN is not turning !!!

Pat:

It sounds like you WANT to go the Kenwood Hybrid route; it can be a lot of fun, and maybe some frustrations, but that's a part of any hobby. There are two or three web sites hosted by hams who are quite knowledgeable about the hybrids. One site is http://www.k9tw.com/how-to-guides. Terry is a regular contributor to this forum and we our thanks to him.

There's even a couple of articles on how to buy a hybrid. These articles show you some simple tests that you can perform to find out if your radio has no faults (rare), minor faults (common) or sever faults (probably rare).

You mention perhaps buying two rigs from someone nearby. Tell them your newness to the hobby, and ask them to demo the radios to you. If they won't plug them in and turn them on, be suspicious. You don't need an antenna to check out much of the receiving side of the radio. The hybrids contain a calibration oscillator which can tell you a lot about your radio. In fact, with a short (5 foot) piece of wire stuck in the center pin of the antenna connector you're likely to hear quite a few stations. I often take a swr/wattmeter and a dummy load with me when I go look at a potential purchase. You're going to need those two items for your ham career (hobby) anyway, so you can buy them even before the radio. If you purchase a working radio before you get your license you can hook up 25 feet or more of wire to a "banana" plug, stick that into the center of the antenna connector and you can listen to hams all over the world. You'll learn their language and how they operate.

Don't forget to plan an antenna installation and the possible need for an antenna tuner.

Good luck and keep us posted on your license purchase.

Arnie,

Here's what I would check first, in order:

1. Check your microphone switch, if you are working phone. I have had numerous old rigs where there was a stuck or intermittent key switch in the microphone, which would stick and keep transmit on. If it still does this in CW with a key it's unlikely to be the mic switch. Fix is to clean contacts (DeOxit or similar -- I like TriFlow) on that microphone. *MOST* of the stuck transmit issues I have seen were the mic key.

2. Check your microphone wires for a loose connection. I have seen a number of microphones where there was an intermittent or cold solder of the PTT wire, where if you twisted the cord the wrong way you'd transmit or untransmit. Disassemble and resolder the cable. It sounds like your rig is in good condition, but I have seen older microphones where the rubber insulation between wires was dodgy and also would transmit or not transmit depending on what was shorting out where. (also have seen a rig fried by a bad mic cord!).

3. Clean the relay (VERY carefully) with DeOxit or TriFlow. Pop the cover off those old relays without breaking the plastic and spray in some appropriate fluid, and then blow out the relay with a compressor or canned air. I've had a few sticky relays where it would get stuck in transmit, too. This is in my opinion also a very likely trouble spot--I had two non hybrid Kenwood TS-430S rigs which would exhibit the symptoms you describe, due to T/R relays that needed to be cleaned. (same issue on the 430S and they band relays -- also tend to get corroded and stick because the relays are not sealed, but that's not a Hybrid).

4. Clean and check the various board interconnects for corrosion on contacts. Though that generally causes a rig not to go into transmit (rather than sticking). Clean with a toothpick and triflow/deoxit. Be very careful if you do this that you do not break any of the aging wires.

5. The next areas I'd look at would be the VOX circuit etc. as there are some electrolytics in there I have had go bad on both my hybrids... but if it's while using PTT I would not think this is an issue (and it's a bit of a pain and potential for damage going that direction). I did have a transceiver which would stick in transmit due to a bad capacitor not draining, but not a Kenwood hybrid in that case. There's some possibility of this given the age of the electrolytics in all of these rigs, IMHO.

I suspect it's one of the easy issues, not the harder ones to debug (but I may be wrong!).

Good luck!

Ben

With wonderful help from Terry and others on this usergroup, I am getting my TS820s up and going to spec..

I see that there are three holes in the left side of the outer case on this TS820s.

In pictures I see on the web, Kenwood put some gray rubber plugs into these holes, and these three plugs are missing on my radio.

Besides a piece of electric tape, any suggestions on what to block them off with?

I don't want the fan in the PA to pull air from these holes and dust up the IF boards.

Thanks, Bruce N4JHY

Not sure if you are looking at an interim antenna for listening before you get the licensing under control. When I started I had
Hammarlunds both ham only and general coverage. The antenna I used was just aluminum foil around the top of the room. My wifewas not real thrilled with the look but I listened all over the world with this. Foil,alligator clip with wire to rig simple and cheap but I DONOT recommend transmitting 100 watts into this .
Good luck with the testing sessions

Hola amigo Ben KK6FUT !

TS820S now ON THE AIR .... followed your advice... and it seems like the little relays had poor contacts .... the inside of the rig in in pristine conditions... I took the trouble of visually checking with a high intensity light and a magnifying glass all the visible boards and especially looking for leaking or inflated electrolytics... and everything looks nice...

Made many 40 meters band SSB contacts this morning and got very good reports... except when I tried to use the PROCESSOR:.. when switching the processor the audio level goes down, and the radio sounds ¨ like talking into a tin can ¨...

Also at 240 milliamps plate current on CW , I only achieve an output of 70 Watts into a professional 50 ohms dummy load...the 6146's idling current is at 50 milliamps... When on SSB, voice peaks go to about 60 Watts on the meter,that should be much higher due to the inertia of the power meter's needle...

Any other suggestions will be most appreciated.... and of course that I send you a big THANK YOU AMIGO !!!

Rodger K1HH
TS-520SE Thanks for the information on meters and other tools I'll need
I'll start looking for them, any special name brand I should look for?.

Also the tip of checking the radio, great to know its working and have the seller run through it with you., always hard to go back and say "Hey" this isn't working, like I always count my money when I make a deal with someone, nude being rude just making sure bills don't stick together or one accidentally miss counted, I do ii as well from time to time.

I'll also be sure to check out the links for Kenwood sites and articles,

Patrick,

I have 4 hybrids here in the shack. Bought them as an adult because using them takes me on a path down memory lane, as does some of the other boat anchors I have on the shelf. So I'm a kool-aid drinker when it comes to these rigs.

However, for a new ham, I would not suggest this series of rigs as a place to start for several reasons. They are old and the mechanical issues mount over time, and in some cases are somewhat complicated to fix. They are old and there are electrical issues that accumulate over time, usually tube swaps and electrolytic failures – generally not too bad. And they are of the manual tune variety which for a new ham is another thing to mess with. Improper tuning can lead to an electrical failure that would need to be fixed. They don't have the sorts of built-in protections as more modern solid-state gear has. And lastly, some of the hybrid models won't work on the WARC bands – something a new ham interested in HF will want to be sure they have access too, especially as we head into a downturn in the solar cycle.

So I guess my contrarian view can be summarized like this. If you love the hybrid gear and don't mind the issues that come with it, then they make very fine radios. On the other hand, if you are looking for something just to get on the air with, want something that can be abused a bit and is not too finicky, then I would point you in the direction of an Yaesu 450 or Icom 7000 or something like that. Something like a Yaesu FT-857d would give you all bands and falls into this entry level category as well as being a very capable box.

Good luck and welcome to a great hobby.

Subject: Re: [TS-520_820_530_830] New Rig Old Timer

Pat:

It sounds like you WANT to go the Kenwood Hybrid route; it can be a lot of fun, and maybe some frustrations, but that's a part of any hobby. There are two or three web sites hosted by hams who are quite knowledgeable about the hybrids. One site is http://www.k9tw.com/how-to-guides. Terry is a regular contributor to this forum and we our thanks to him.

There's even a couple of articles on how to buy a hybrid. These articles show you some simple tests that you can perform to find out if your radio has no faults (rare), minor faults (common) or sever faults (probably rare).

You mention perhaps buying two rigs from someone nearby. Tell them your newness to the hobby, and ask them to demo the radios to you. If they won't plug them in and turn them on, be suspicious. You don't need an antenna to check out much of the receiving side of the radio. The hybrids contain a calibration oscillator which can tell you a lot about your radio. In fact, with a short (5 foot) piece of wire stuck in the center pin of the antenna connector you're likely to hear quite a few stations. I often take a swr/wattmeter and a dummy load with me when I go look at a potential purchase. You're going to need those two items for your ham career (hobby) anyway, so you can buy them even before the radio. If you purchase a working radio before you get your license you can hook up 25 feet or more of wire to a "banana" plug, stick that into the center of the antenna connector and you can listen to hams all over the world. You'll learn their language and how they operate.

Don't forget to plan an antenna installation and the possible need for an antenna tuner.

Good luck and keep us posted on your license purchase.

If you do the 520 series, you will need an external SWR/Power meter. The Bird wattmeters look right at home the these Kenwoods. Palstar <http://www.palstar.com/en/pm2000a/> makes a nice wattmeter with peak and average with SWR. Daiwa also makes some nice meters. Take a look at the usual ham retailers (DXEngineering, Ham Radio Outlet, etc...) to see what is available. The external wattmeter is helpful with loading the rig plus it is always nice to see the SWR and power out you are getting while transmitting. The radio, however, is capable of being operated without an external meter.

You will need a dummy load capable of taking the load you will send it. You can get away with something smaller now or just buy the legal limit 1500+W type if you think you may get an amp in the future. You will need an antenna tuner likely depending on the antenna you choose. I made an OCF dipole and several trimmed dipoles for 20, 40 and 80M initially and my TS-520S was able to match those trimmed antennas (and the OCF) without the need for a tuner. It seems pretty robust in that regard My tuner is a matching to the hybrid era Heathkit SA-2040 that can take the legal limit so it can use it with an amp. Don't forget also all the coax jumpers to connect that equipment so learn to make them and attach the appropriate connectors or buy them.

Don't forget about the other half of the antenna and figure out how you are going to ground everything and get the coax or ladderline into the house or shack. So there will be the expenses of copper braid and wire and groundrods and perhaps lightning arrestors. Feedline can be expensive (or not depending on your tastes). There are many vendors that sell coax and ladderline. Don't forget you will need a way to log all these future contacts you will make so either paper and pen or electronic logging. Having the radio right next to a PC is helpful (even if not CAT driven) for checking band conditions, spotting networks, QRZ etc.

Lastly if you go the hybrid route, you will quite likely get the itch to "complete" the station and will soon be hunting down the digital display (520 series), the speaker that came with the series, and the external VFO. That will add a fair bit the base price of just the rig (several hundred dollars likely). The built in Kenwood speaker is fine but is a bit tinny. An external speaker is very helpful and makes for enjoyable listening.

73 and best of luck -
Dennis NS8H

http://www.dxzone.com/catalog/Technical_Reference/Dummy_Loads/

> Feedline can be expensive (or not depending on your tastes)....

Made ~25 metres of ladder line with 16-gauge wire salvaged from the recycle center, small UV-rated (outdoor) zip-ties, and spacers from the electric fence section of the local farm-and-feed store. Cost me about eleven bucks, would have been more if I had to buy the wire instead of scavenging it. (Copper by the pound is still pretty cheap.) An hour or a bit less straightening and coiling the wire, and about two hours construction, which included the time spent boring holes in the plastic spacers with a drill mounted in a Dremel hand-held tool and zip-tying the spacers to the wire.

If you have access to wood doweling cheaper, that works as well (if you varnish it to keep the rain out). Other plastic items similar to those fence spacers will work quite nicely, look around your hardware outlets and the local feed stores for ideas.

(They also sell spacers and other bits specially for Hams to make ladder line, if your budget can handle it.
http://www.dj0ip.de/open-wire-fed-ant/d-i-y-ladder-line/
for an example. There are others; look around a bit and one of them might suit you better.)

Ham radio (despite contrary opinions, and unlike some other hobbies) really isn't a competition to see who can own the best or most expensive gear. The idea is to get on the air with what you have, can build, or can afford, enjoy yourself making contacts, and as time and money permits, try something more, or something else.

If you like some kind of movie instead of reading descriptions and diagrams,
https://www.youtube.com/watch?v=yBT84RPglzg

Personally, I'll take a diagram and some words any day. But then, I'm weird...

Prof:

I didnt see any responses. If duplication disregard.

Couple of comments and questions.

1. Why are you loading to 240ma? The TS820S is rated at 160 watts dc input power in CW mode. Assuming 800vdc plate voltage you are loading to approx 190 watts dc input. So you are exceeding the maximum plate dissipation of the Final tubes. 200ma is Ip limit noted in your operating manual. All the hybrids can be repeatedly and routinely loaded beyond maximum specified dc input power and survive if done quickly, but silly to do so. What saves the tubes is the fact that you will be using SSB and CW modes which are low duty cycle. Probably around 30% to 40% depending on your voice characteristics and keying speed. I would not make it a practice to load to 240ma. One other thing to check is the resistance value of the Cathode meter shunt resistors. Should be 5 ohms. If drifted high you will be seeing a false high Ip indication. Might not be loading to 240ma.

2. Assuming you are loading to 240ma on all the bands into your dummy load do you see 70 watts or less output on all the other bands? If so, couple of possibilities include Final tube cathode emission is down (soft tubes) or Plate HV is less than approx 800vdc key down. If HV is good then try another set of Final tubes. If still low on all bands then may have bad Plate block and/or RF Bypass caps inside the PA cage at the RF Plate Choke.

3. You state only seeing 60 watts on your wattmeter on voice peaks. Is the wattmeter a true Peak reading meter or an Average reading wattmeter? If an Average reading meter which is more common then you are overmodulating. Mic gain set to high, close talking,yelling into the mic. Normal average wattmeter deflection on voice peaks would be 25 to 30 watts maximum. Where is the ALC deflection? Where is the mic gain setting? Fortunately the TS820 in addition to ALC employs a RF negative feedback circuit so between the two it is hard to overdrive and produce high IMD products (splatter). If you are using a Peak reading wattmeter then 60 to 70 watts on voice peaks is correctwhen your max CW output is 70 watts.

4. It sounds like your RF processor is misaligned which is very common. The Service Manual is wrong and previous owners may have adjusted the 455khz oscillator to 451khz which doesnt bring the audio in to the passband of the 455khz filters. For a quick and dirty test set the oscillator to 453khz and see if that makes an improvement. If so, then suggest you to perform the entire alignment which includes nulling the carrier at the 455khz Balanced Modulator, peaking the 455khz IF transformers, and driving the BM with 1000hz and 300hz to set the 6dB roll off. This adjusts the frequency response for maximum compression. Should be able to see approx 20dB on comp meter with comp pot advanced to 1200.

Hola amigos ! My two days ago revived TS820S performed quite nicely one day, then Wednesday morning it started to act up by drifting frequency both when receiving and when transmitting.

The drift is obviously related to NO LOCK PLL condition.... !!!

I opened the top lid, and blew hot air all around at high speed, assuming that humidity at the place it was in storage was acting up... but except for blowing dust away, it did nothing to the frequency drift problem.

I do not have the technical manual of the TS820S where supposedly the procedure to check and adjust the complex discrete components PLL circuit should be available...

Information on how to fix the problem will be most appreciated as the rig is now useless... By the way, the drift stops when you select the RIT option on receive... seems like the PLL locks up in sync but the drift when transmitting continues.

I was amazed by the excellent state of conservation of this decades old rig.... that was revived from long term storage by carefully feeding it AC power line voltage by means of a VARIAC voltage variable autotransformer...

Any suggestions and ideas on what to check will be most appreciated...

BTW, when it was working OK, Tuesday evening, I work UX5IO , Roman in Ukraine , several USA stations and earlier in the day many Cubans on 40 meters SSB...

56026. Tired TS-820?

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-11-24 02:30:51 UTC
From: dr.intrepid@...
Topic: 56026 Message: 56026

Happy Thanksgiving all,

I need some advise on trouble shooting my TS-820. Over the past few months I am only able to get 60-70 watts on all bands through a dummy load on CW. I am putting out less than 40 watts on SSB (again on all bands).

Here is information that I have recorded.

The bias is set at 60 mA I am tuning the rig to about 200 to 220 mA On CW, when tuned the Heater Voltage is 800 On Transmit (CW) the panel meter is reading 230 mA. The SWR/Power meter is reading 60 watts. This information is consistent on all bands, through a dummy load. Inside the transceiver there was a note that indicated that the three tubes were replaced in the 1990s. However, I do not know the history of the rig since that time to about 2015 when I bought it.

Any suggestions are greatly appreciated.\

73,

David Richer, K6VGO

56027. Are my TS-820's Tubes Tired?

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-11-24 04:26:34 UTC
From: dr.intrepid@...
Topic: 56027 Message: 56027

Over the past few months my TS-820 seems to be losing power on transmit. When I tune up and transmit on a dummy load, external power meter is showing less than 80 watts, even with the Carrier maxed out. When I am transmitting on SSB, my peak power is less than 40 watts, even with the mic gain maxed out.

The following is the readings from the meter on my 820 when I am tuning:

The bias reads 60 mA When setting the drive, the meter generally reads > 300 mA on all bands I generally set the CW-IP between 200-220 mA On CW transmit the meter reads 220 mA. However, my SWR/power meter reads only 60-70 watts (again on all bands). The HV reads 800 volts, on all bands. On SSB, I always have to set the mic gain full. The 820 meter peaks out at 120 mA while the SWR/Power meter peaks at 30 watts forward (both on a dummy load and antenna, with 1:1.4 SWR)
Is it possible that my finals are tired? There is a tag on one of the 6146bs that they were replaced in 1996. I do not know the history of this rig. The service manual suggested that constant low power may be related to worn out finals.

Is there any additional diagnostic tests I can do?

Any assistance is greatly appreciated.
73,

David Richer, K6VGO

56028. RE: Yet another technical problem with the revived TS820S. external VFO does not work

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-11-24 05:08:57 UTC
From: Prof. Arnaldo Coro Antich
Topic: 56028 Message: 56028

Dear amigos:

I have not yet fixed the frequency drift problem... and a new one has come forward...

Thought that it would be a good idea to test the external VFO unit that also seems to be in very good state of preservation, except for some rust showing up at the top of the cabinet.

To make things short... the external VFO does not work...

When I opened it, seems like it was the first time ever that it was inspected visually inside... Measured at the little PC board with a Digital Multimeter and I get near 9 volts at some pins, and 5 volts at another pin... The connections to the pins do not look like it they were soldered.... seems like just wire wrapped around the pins...

Yes, I did checked with the VFO controls at different positions and despite red LEDs do light up, when switching the knob at the front panel of the external VFO unit...the digital read out goes blank and nothing is heard or transmitted !!!

As always help will be most appreciated amigos

Hola amigos: TS820S frequency drift ... no luck and no lock !!!

Have any of you had to try to solve uncontrolled frequency drift on all bands including the JJY 15 mHz segment ?

The other minor problem is that the processor , when connected produces very bad quality transmission audio...

Suggestions on how to fix the frequency drift are most appreciated because it makes the rig impossible to use....

I recommend you first check and if necessary, make adjustments to the AF AVR Unit's 9VDC and 3.3VDC levels as discussed on page 44 in the TS-820/820S service manual.
The VFO, both internal and external, are powered from the 9VDC supplied by the AF AVR Unit board.

I have the TS-820/820S service manual on my website.
http://w5rkl.com/wp-content/uploads/2014/04/ts-820s_service_manual.pdf
Click the above link, allow the file to download to your computer then go to Adobe reader page 48, service manual page 44, and perform the 9VDC and 3.3VDC check and adjustment as stated in paragraph

"1. Adjustment of Power Supply".

Arnie,
The drift you are seeing in your TS-820 is not caused by the PLL Unit changing states to "Unlock". If the TS820 PLL Unit changed to an "Unlock" state then the dial and meter lamps would still light, the relays would click/energize by using the SEND switch or PTT microphone button, the digital display, if installed, would go dark showing only the decimal point, no frequency, and both receive and transmit would no longer work..

Drift in your 820 can easily be caused by instability in the AF AVR Unit's 9VDC source voltage that powers the internal and external VFOs. If the VFO's drift then the 820 will drift.
The VFOs operate over a frequency range from 5.5Mhz at the bottom of ALL bands to 5.0Mhz at the top of ALL bands. The VFO does not change frequencies when the band switch changes as some hams tend to be mistaken. The VFO 5.5Mhz to 5.0Mhz frequency tuning range is the same regardless of the band switch setting.

The TS-820's normal frequency stability is 100Hz after a 30 minute warm up and +/- 1Khz per hour after a 1 minute warm up (see the TS-820 specification page, page 3 in the operator's manual).

73Mike W5RKLhttp://www.w5rkl.com/

Happy Thanksgiving all,

I need some advise on trouble shooting my TS-820. Over the past few months I am only able to get 60-70 watts on all bands through a dummy load on CW. I am putting out less than 40 watts on SSB (again on all bands).

Here is information that I have recorded.

- The bias is set at 60 mA
- I am tuning the rig to about 200 to 220 mA
- On CW, when tuned the Heater Voltage is 800
- On Transmit (CW) the panel meter is reading 230 mA. The SWR/Power meter is reading 60 watts.
- This information is consistent on all bands, through a dummy load.

Inside the transceiver there was a note that indicated that the three tubes were replaced in the 1990s. However, I do not know the history of the rig since that time to about 2015 when I bought it.

Any suggestions are greatly appreciated.\

Topic: 56036 Message: 56036

First of all Happy Thanksgiving to everyone in this forum. I am trying to repair a nice TS-830S I bought on eBay. The radio works fine in receive with good sensitivity but there is no transmit. Here are the symptoms and what I have done so far.

With the meter on IP and the mode in SSB I can adjust to 60 ma resting current. With the meter on AVC and in Tune mode, when I flip the Send switch, the needle moves to the top of the AVC line and sits there. Adjustment of Drive has no effect, and also adjustment of Carrier has no effect. This behavior occurs on all bands. HV in receive is 900 volts and a previous owner had replaced the HV caps. I tried the shotgun approach of replacing the driver tube and finals to no effect.

Now I would appreciate advice on a systematic approach to solve this problem. I have the service manual. Here is the extent of my service equipment:

DMM
Home made Rf probe
Pomona socket

Again Happy Thanksgiving!

Scott, N6CIC

Hello David,

My 820 was also low on output so I replaced the finals and still low output, I had checked the driver tube on my tube tester and it checked out fine and also did the tests from Terry's site. Turns out it was the driver tube once replaced I had full power again.

Good luck

Scott:

It sounds like you have no or low ALC buss voltage which means no dc control or servo voltage to Q29 TIF amp on the IF board.

The fact that you have receive tells you that you do have RF-1 at AF board molex connector 10.

Go to the AF board Molex Conn 10 Pin 3 and measure the ALC bus voltage. If RF-1 reference voltage has been set to 3.6vdc your 10 meg DMM will pull it down to approx 3.0 vdc.

If you have 3.0 VDC at Conn 10 at AF board then go to the IF board Molex Conn 5 Pin 3 and measure. If no 3 vdc there then gently wiggle the molex connectors at each end. May have to remove and reseat the molex connectors.
Can also apply 3vdc from couple of series 1.5vdc batteries to the ALC bus and see if TX comes alive. If it does, most common problem would be bad molex connectors, pad solder at pin pad, cracked foils at pin pad trace transition, or a shorted Q30 ALC meter FET.

Usually a shorted Q30 would cause the ALC to peg full scale. If it is only deflecting to the top of the ALC range that sounds more like a high resistance connection in the path and not a shorted Q30.

Hi Bob,

These problems are typically caused by the HET OSC crystal being off frequency, in your case the 80 meter heterodyne oscillator crystal is most likely off frequency by at least 2Khz.

If you have or have access to a frequency counter you can connect it to the rear panel's "HET" RCA socket then put the band switch to 80 meters and power up the TS-520S. The frequency counter will display the 80 meter heterodyne crystal's frequency. The 80 meter heterodyne oscillator crystal frequency is 12.395Mhz.

You might drop Walter Dilley an email, walter dot dilley at gmail dot com, to see if he has the 80 meter het osc crystal.

56046. REVIVED TS820S now almost matching all normal operating parameters except ....

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-11-25 21:26:44 UTC
From: Prof. Arnaldo Coro Antich
Topic: 56046 Message: 56046

Yes amigo ! Almost a miracle... The old TS820S is now on the air, and also almost matching all normal operating parameters except two:

1. Power output does not go above the 60 Watts on CW from 160 to 20 meters and less on 15 and 10 meters....

2. The RF compressor does not sound OK as verified by many reports... It obviously needs a complete (and rather complex) alignment procedure that requires the use of sophisticated test instruments and expertise on how to do it...

For the benefit of those attempting to revive a Kenwood Hybrid like the TS820S coming from a long time storage , here are some useful tips...

Clean the rig with clean air at not too high pressure... just enough to blow off the dust. Then use a hair dryer and blow hot air over all the rig....do at least two sessions leaving no less than half an hour between them... because that seems to help to remove humidity from deep inside the equipment.

Apply power line via an adjustable AUTOTRANSFORMER (Variac or similar) and start at 20 volts AC.... Do not rush , keep the 20 volts AC for no less than 6 hours... then move up to around 50 volts and if possible monitor the AC current with a clamp AC ammeter... Run 50 volts for a full day... it will help the slow restoration of high voltage electrolytic capacitors in the 800 volts supply !!! And others as well...

Then move to 100 volts AC and it is time now to test the receive mode... You can use a signal generator connected to the antenna terminal, or as I did connect an actual antenna (a 40 meters wire dipole in my case) and search for signals..)

Then try to transmit with the CW mode and the carrier control potentiometer at an almost zero setting, while the rig is connected to a 50 ohms dummy load...

My problems started when I found that the rig was drifting badly on both transmit AND receive modes.... So I had to go through an extensive fault finding procedure that helped to fix the problem after setting the plus 9 volts and the plus 3.3 volts on the AVR/AUDIO board.

Also checked the wiping contact of the VFO variable capacitor ...

Now drift is practically as per the rig's original specifications....

Have worked DX.... on 40 meters during the evening hours, several European and American stations and received good reports using the Kenwood MC50 microphone....

Thanks a lot to all list members who helped me achieve this success !!!

After repairing the dreaded ALC problem on a friends late serial number Kenwood TS850s, I got a chance to run it through its paces on my op table.

Its a nice radio, but, I much prefer my newly acquired TS820s by a long shot.

The sound of the 820 receiver is just so much nicer to listen to for hours on end.

I'll tell you, that after repairing several problems with my TS820s, with help from several on this usergroup, especially Terry, I have come to the conclusion that the TS-820s is a work of art !!!!!

It is fun to work on, is so beautifully built, and super fun to operate.

BTW, my stereo in my living room has tubes, and I only play records.

The digital stuff isn't all it is cracked up to be!!!!!!!!!!!!!!!!!!!!

Bruce,

they have yet to master taking billions of ones and zeros and convert it to something as natural as analogue. My 830's sound much better than my modern gear. And I also have a hi-end vinyl set up here and totally agree.

After repairing the dreaded ALC problem on a friends late serial number Kenwood TS850s, I got a chance to run it through its paces on my op table.

Its a nice radio, but, I much prefer my newly acquired TS820s by a long shot.

Hola amigos:

The radio started to make noises and a bad smell filled the room... I was running the carrier on CW feeding a 50 ohms dummy load with about 20 Watts out, when suddenly the meter lights went on and off , the frequency read out went blank, and I ran to the AC power line plug to disconnect it...

After removing a zillion bolts that hold the two covers and the cage of the 6146's , I used the nose smell detector... that took me to the 6146's....One of the tubes has a clear indication that it shorted inside... black spot , really black, not the typical getter deposit... Then I found out that the tubes were not SE2001 or equivalent 6146B's , but 6146A and of two different manufacturers...

Removed the tubes, connected the loudspeaker and the antenna, and the radio started to receive pretty well, but with the digital read out frozen on 9.000 and the 0.figure changes as I move the dial... The crystal 25 kiloHertz marker checks OK, and I am able to receive on 10, 15, 20 and 40 meters ...

Also, just before the breakdown , the Compressor knob became useless, something that had not happened before, because I was seeing the compression on the meter, and also receiving reports from 40 meter local stations that the compressor was surely working...

The RF processor when connected by means of pulling the knob out, sounds simply horrible... very tin can audio !!!

Need help plus advice on how to fix the digital frequency readout, that is operating intermittently ... reading OK for a while and going back to the nonsense 9.000 display....

Will try to find a pair of 6146's that I seem to recall where in a box with a 12BY7 ... the box may be difficult to locate in the many boxes that still remain unopened when my shack and workshop had to be moved to the garage , so wish me good lock...

One final comment, the little fan seems to be in bad need of a light lubricant... that it is going to receive when I find the light oil dispenser , also to be located in the garage !!!

You can read/study the differences between the 6146A and 6146B by clicking the following links:
6146Ahttp://w5rkl.com/wp-content/uploads/2014/04/6146A-GE.pdf
6146Bhttp://w5rkl.com/wp-content/uploads/2014/04/6146B-RCA.pdf
The big difference between the two tubes are the Plate Dissipation ratings.
The 6146A plate dissipation rating is 20 watt CCS and 25 watts ICAS

The 6146B plate dissipation rating is 27 watts CCS (Continued Commercial Service) and 35 watts ICAS.
ICAS stands fro "Intermittent Commercial and Amateur Service".

If you are still unsure then click the following link for further information.

My FT990 is full of digital boards and microprocessors, and it sends a CW note out as pure as my DX20 or TS520(no S) did, And the receiver sound is clean, as well, and makes a pure note in the speaker, if the transmitter carrier is clean !
Vinyl recordings can have surface imperfections that make clicks and pops, no matter how carefully you handle and store them, This is like receivers picking up thunderstorm lightning static on 80M . My radio is Ham Radio...CW is Real Radio 73, John...K8JD

Dear amigo: The very old TS820S that I am trying to make it work... did worked OK one day, then it started to show one problem after another.

Now I am able to receive on 40 meters , also on 20, 15 and 10... B

But this afternoon it stopped transmitting... I measure the grid bias of the 6146's that goes to minus 60 V on transmit mode... and a to minus 99 volts voltage on receive mode

The front panel meter shows 800 volts or more when the PTT is activated... BUT now, there is no plate current indication on the front panel meter when the PTT is activated.

I can still hear myself on the local monitor... but there is no output at all on any of the modes CW, USB , LSB or RTTY.

Can not find the location of the antenna switching relay !!! I thought that it may be not working properly ....

As a type this, I am hearing 5 9 Plus signal from a CO8 call area ham more than 500 miles away ... this is on 40 meters, but when going to transmit by activating the PTT, there is no plate current showing on the panel meter, and also no RF out indication...

The cathode resistors on this rig are 4.7 ohms at 1 WATT, one at the cathode of each 6146. Also checked the grid resistors and they are OK...

Just checked now the screen grid voltage when on transmit mode and it is ZERO, and that may be the reason why there is no plate current !!!

Any ideas on how to continue tracing the fault ?

Arnie,

If the final tube screen voltage is zero then there will be zero no signal idling current in any mode. You should still be able to see ALC in TUNE mode as the screen voltage has noting to do with grid current.

Check to ensure the rear panel Xverter switch is in the OFF position and the SG switch is in the ON position.

The antenna relay located below the chassis between the final amplifier PC board and the rear panel inside a small metal enclosure, has nothing to do with the final amplifier screen voltage.

The final tube screen voltage originates from the Rectifier Unit's "210A" terminal so check that first then check the above switches to ensure they are in the correct position. IF the Rectifier Unit 210A terminal voltage is zero then D6 on the rectifier board is burnt open.

If the 210A diode D6 on the Rectifier board is found to be burnt open, it's possible that C24A, 22ufd 450VDC cap may be shorted internally. C24A is part of the dual capacitor caps located between the IF Unit board and the rear panel on the left side of the transceiver (transceiver front panel facing you). There are 2 dual 22ufd 450VDC caps on the top left side of the transceiver between the IF Unit board, 5V AVR board and the rear panel. They are typically "BLACK" cardboard covered caps. Each cardboard cover contains 2 x 22ufd at 450VDC capacitors.

You can see how the final tube screen voltage path is routed to the Final Unit by studying the voltage path from the Rectifier Unit's 210A pin to the Final Unit's "SG" pin and all switches in between.

Dear Mike;

I still do not get any plate current reading... the diodes on the board where there are two small electrolytics show 260 volts and 330 volts... But at the screen grid antiparasitic resistors located at the octal sockets of the 6146's there is no DC voltage on transmit...

My copy of the circuit diagram is very small in size and difficult to see !!!

What may be happening from the rectifier board to the screen grids that cuts the screen grid voltage seems to be difficult to find...

The panel meter reading on the ALC position while in Tune mode is very small, just barely above zero and it does not move when pressing the PTT and talking....

Now I need to prepare a big magnifying glass and a good light source to try to follow the wires from the screen grid antiparasitic resistors...

I now see that the antenna switching relay has anything to do with the screen grid voltage feed ...

Will take a little break, and continue trying to bring back the TS820S so that it will transmit !!!

John,

There is just something nice sounding in a single conversion radio like a KW TS820s.

As far as LP records, if you were to go to one of the high end audio shows, where companies show off their $100,000 speakers and $50,000 amplifiers, most use vinyl (records) to audition their equipment. There is a reason for this. They sound better. Period.

Thanks for your input/

Bruce N4JHY

Arnie,

You can download the TS-820 service and user manuals plus a TS-820 high resolution schematic, from my website. Click on the following links and the manuals and schematic will download to your computer.

TS-820 Operator manual
http://w5rkl.com/wp-content/uploads/2014/04/TS-820S-Operators-Manual.pdf

TS-820 Service Manual
http://w5rkl.com/wp-content/uploads/2014/04/ts-820s_service_manual.pdf

TS-820 High Resolution schematic
http://w5rkl.com/wp-content/uploads/2014/04/TS-820-hi-res-schematic.pdf

You can trace the Rectifier Unit's "210A" voltage path using the high resolution schematic and the FINAL Unit schematic found in the TS-820 service manual.

Hola Mike

Thanks a lot for the follow ups....I found the two dual 2 X22 mff capacitors... The one closer to the edge of the chassis reads plus 260 volts on one pin, has another pin with a black wire connected to a ground pin that is soldered not only wire wrap connection... BUT, the other pin that is connected to a brown wire reads 0 ZERO volts both on receive and on transmit !!! So there is no voltage reaching that capacitor...

Just downloaded the high resolution schematic, and using the computer magnification feature to try to trace the path that leads to that filter capacitor...

Of course that I am very familiar with vacuum tubes theory, so I understand that without screen grid voltage applied, zero volts, the idling plate current should be very small, but in this case the panel meter is reading zero plate current on the transmit mode...

Will take another little break to refresh the eyes and will return to the kitchen table repair shop... that must be cleared before supper HI HI ...

BTW reception is very good on 40 meters as sunset is approaching here in Havana.

Arnie,
Loss of final tube screen voltage does not result in a "reduction" or "lower" IP current. Loss of final tube screen voltage results in zero IP current.

Loss of screen voltage makes the final amplifier screens to appear "negative" in respects to the "Plate". This "Negative" screen potential blocks the flow of electrons to the screens AND plates which is why the IP meter is resting at zero in any transmit mode!!!

Each of the four 22ufd 450VDC caps are "independent" of each other and are not wire in series. There is one for the 210A, one for the 210B, one for the 300A, and one for the 300B. Look on the schematic and you will see how each one is connected to the 210A, 210B, 300A, and 300B rectifier unit terminals. Te resistor, R7 (470K 1/2 watt) is connected across C23A's positive and negative terminals.

If the 210A diode D6 on the Rectifier board is found to be burnt open, it's possible that C24A, 22ufd 450VDC cap may be shorted internally. C24A is part of the dual capacitor caps located between the IF Unit board and the rear panel on the left side of the transceiver (transceiver front panel facing you). There are 2 dual 22ufd 450VDC caps on the top left side of the transceiver between the IF Unit board, 5V AVR board and the rear panel. They are typically "BLACK" cardboard covered caps. Each cardboard cover contains 2 x 22ufd at 450VDC capacitors.

You can see how the final tube screen voltage path is routed to the Final Unit by studying the voltage path from the Rectifier Unit's 210A pin to the Final Unit's "SG" pin and all switches in between.

Topic: 56063 Message: 56063

Dear amigos ;

The TS820S saga goes on and on !!! Testing on transmit mode, heard something arcing, then no more transmission... On any mode....

Found out that there is no screen grid voltage on the 6146's linear power amplifier stage... so no plate current indicted on the panel meter...

Very difficult to follow the wiring of this radio... One of the two 2 X 22 mfd capacitors , the one located near to the chassis shows one of the capacitors with 260 volts , but the other capacitor, the one with the two brown wires shows 0 volts on it... This electrolytic is connected with one brown wire to the screen grid switch, and the other brown wire, very difficult to follow, goes somewhere else... It seems like the arc over on one of the 6146's has damaged a voltage divider network that drops the plus 260 volts or so to the 210 volts that must feed the screen grids on all transmitting functions of the radio... The screen grid switch is in the ON position, but there is no voltage on it when sweeping across all the MODE switch positions....

Topic: 56063 Message: 56064

Arnie,

The final tube screen voltage drops when current flows in the tube. There is no voltage divider network that drops the screen voltage from 260VDC down to 210VDC, the voltage drop across the tube's screen is what drops the screen voltage.

I also said you should check the Rectifier Unit's "210A" terminal DC voltage. The voltage will be there as long as the transceiver is powered ON and whether the transmitter is keyed or not. If the Rectifier Unit's 210A voltage is zero I said to check D6 on the Rectifier Unit. If D6 is open then the Rectifier Unit's 210A voltage will be zero which will cause the Final Unit "SG" terminal to be 0VDC AND both final tube screens, pin 3, voltage to also be 0VDC!! Since the final tubes have zero screen voltage then the driver tube also will have zero screen voltage (measured at the RF Unit's "210A" terminal.

Here's how to trace the wiring from the Rectifier Unit's 210A filter capacitor positive terminal to the Final Unit's SG pin and ultimately pin 3, screens, on the final tube sockets using the schematic diagram. Everything I say in the following, you can follow using the schematic you downloaded from my website. The discussion starts at the Rectifier Unit on the SCHEMATIC.

First, one Brown wire from C24As positive terminal goes to the left and up along the left side of the Rectifier Unit to the Rectifier Unit's "210A" terminal on the SCHEMATIC. You will notice another wire leaving the Rectifier Unit's "210A" terminal, going to the "Left". If you trace that wire "on the schematic", you will notice it will goes to the left then up and then to the right then up to the RF Unit's "210A" terminal. This provides the DRIVER tube on the RF Unit with screen voltage.

The other Brown wire connected to C24A positive terminal, goes to the right along the bottom of the Rectifier Unit on the SCHEMATIC then turn UP along the right side of the Rectifier Unit and continues up and then turns to the right for a short distance then up and finally to the Xverter switch's "OFF" terminal. The Xverter switch is a "SPDT" switch with the movable element is show connected to the "OFF" terminal. Notice the Xverter moveable switch element has 2 wires connected to it. One wire goes to pin 10 on the Xverter socket while the other wire goes to a "T" connection to the "left'. Follow the wire "up" from the "T" connection, to the "1.8/JJY" switch S4-5. Notice the wire leaves JJY S4-5 switch and connects to the Final Unit's "PD2" terminal. The PD2 terminal connects to the "PD1" terminal on the Final Unit. Follow the wire from the PD1 terminal down and then to the LEFT where it connects

to the MODE switch S6-8. The moveable element of switch S6-8 connects back to the right then up to the SG switch S18 "ON" terminal. With the SG switch set to ON, normal screen voltage is applied to the Final Unit's "SG" terminal and ultimately to the final tube's screens, pin 3 on the 8 pin tube sockets!!!

I do not suspect there is a failure in the physical wiring harness. It appears there is a failure in the Rectifier Unit "210A" output voltage. This can be caused by C24A shorting internally causing diode D6 on the Rectifier Unit to fail, burn OPEN, causing loss of Rectifier DC at the 210A terminal. I would check C24A for an internal short.

John,

What Bruce is trying to say is, there is no technological way for digital to reproduce the harmonics of an analog system. CD's don't hold a candle to Vinyl, just as digital "processed" audio can't compare to a full tube system, which is still superior to a hybrid, which in audio, is superior to a modern day DSP hyper processed analog signal. Yes, it has no noise, but it looses it's "character" in the process. I'll match my 830's receiver against any modern day receiver. I still get an audible tone out of my receiver while injecting a 1khz modulated tone at 50% modulation at -135dbm.

56066. TS-520 CW Car control does not change output

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-11-27 19:45:38 UTC
From: waifian@...
Topic: 56066 Message: 56066

Hello,

I have a ts-520 I have been working on for some time. I have most of the issues sorted I think.

The current issues are related to transmit. One thing I noticed is that the car control will do nothing to the output level on cw. Using an oscilloscope and measuring the input of q1 on the IF board the level does change with the car control but so does the bias. The output of Q1 remains constant I think due to the bias adjusting with the change in carrier. Q1 was one of the bad parts I replaced with a substitute dual gate MOSFET. The MOSFET substitute used throughout the rig is a BF992,215 smt part that I made an adapter for. The output does appear the flutter a bit when car is around 9 O'clock.

The other thing is on SSB the only report I was able to get was that I sounded distorted like I was off frequency and cutting out. Others just complained of someone causing qrm or having a "scratchy mic". I found that on the bench on upper side band only the output pulsates occasionally with no Mic connected and mic gain set to zero. Carrier is balanced to the best of my ability and this does not happen on Lsb.

This is all into a 50ohm dummy load for testing. No problem with actual output power, finals seem strong.

Receive seems to work great now.

Summary of what was not working when I got the rig:
Rig would power up with full scale deflection of the meter no audio, basically DOA

9v regulator(I think this took out all the other stuff)
-Replaced whole discreet circuit with a 2% lm7809
- agc bias set to 3.3v using fluke 189.

VFO
-buffer transistors bad replaced with 3904s, q1 was bad replaced with j113 with a diode across r1 for stable amplitude.

Carrier board
-one or both transistor were bad can't remember, replaced with 3904s

IF board
-Q1, Q7, Q8, Q9 were bad, used the above mentioned substitutes.
-replaced Q2 while trying to figure out current issues. No effect

RF board
-Q5 was missing, replaced with BF992

2 of board diodes by the carrier board were also shorted, replaced with a pair of small signal diodes.

Hope someone can help. It's been alot of work and I don't want to abandon it.

Thanks,
Nick, AC9LF

56067. Stereo headphones with TS-830S

Ed,

That may be true, but you do NOT get stereo out of the audio jack, you
get mono out of each ear.

You can get a variety of adaptors that take the more common 1/8 inch stereo earphone plug and internally connect and plug in to a monoural single circuit mono 1/4 inch earphone jack found on older radio equipment. This internal arrangement in the adaptor puts the same signal into both ears. My radio is Ham Radio...CW is Real Radio 73, John...K8JD

Hi John,

A few moments with the TS830S schematics will give you all you need to know. Right in the centre of the circuit you'll find the phone socket. You can see it is a stereo socket - Pin 9 is the sleeve (ground), pins 8 & 4 are the tip and the ring and you can see both pins are fed by individual 100 ohm resistors R20 & R21. Note that the left ends of these resistors are joined and go to pin 2 which is a switch to disconnect the internal and external speakers. You can already determine from this part of the circuit that we are dealing with a mono signal. However for the sake of this exercise follow the heavy black line from the junction of R20 & R21 back to its source. You will see it goes back to Q4 via L1 and C34. Q4 is a single mono audio amplifier.

So, to answer your question, you can plug in stereo headphones using a 1/4" jack plug or a 1/8'" to 1/4" stereo adapter if required. What you hear in the left ear is exactly what you hear in the right ear a mono signal. If you don't hear a signal in both ear then perhaps you have an issue with the phone socket.

Joe, WB7UQU - maybe you have a problem with the phone socket in your rig?

BTW, I think some rigs allow you to hear different signals in each ear (Maybe FT1000MP?) but even then it is a mono signal in each ear.

Regards

Lou

From: bfeaver@...
Topic: 56078 Message: 56078

I am restoring this TS-820S and am finding that the frequency in receive is say 7.195 and when I transmit the frequency on the frequency counter on my antenna system is 7.194 LSB

If I am working PSK and the receive frequency is 14.070 then the frequency off the antenna is 14.072 USB

what is the alignment to get these to match up better?
I have all the manuals and equipment to do the task just cant get is straight from the service manual

Any help would be much appreciated

Thanks

Ed,

You should get that, especially if you buy a 3.5mm F TRS to 1/4" M TS adapter.....should have both L and R tied together on the tip of the TS jack.

56080. Hybrid Net Update (November 27, 2016)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-11-28 04:22:31 UTC
From: Mark Gilger
Topic: 56080 Message: 56080

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by me, WB0IQK. There
were 17 stations checking in under fair band
conditions. There were 2 new stations checking in: KM4ZFR, and KC6IKI.

We had the following number of radios checking in.

3 running TS-520(x)
4 running TS-530(x)
1 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running TS-515
0 running 599 twins
0 running TS-900

He was running a TS-830S with an Drake L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
22 stations checking in good band conditions.

We had the following number of radios checking in.

3 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830S + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 ☐ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins
Nov. 2015 ☐ Oct 2016 Saturdays total 807 check-ins, Sunday total 628 check-ins

November 2016, Saturday net total = 80, Sunday total = 68 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo

I'm changing my recent statement about D6 on the Rectifier Unit..
The 210A supply has 2 filter capacitors, C24A and C24B. Both filter capacitors are in "one" can (dual 22ufd 450VDC). D6 rectifies the AC voltage into pulsating DC voltage that is then applied to filter capacitors C24B and C24A (see the Rectifier Unit schematic).

Based on Arnie's recent post, he states he measures +265VDC on what appears to be C24B positive terminal.
Arne then said he measured the voltage on what appears to be C24A positive terminal which has 2 brown wires, and found "0VDC".
C24A positive terminal connects directly to the Rectifier Unit's "210A" supply "output" that supplies the screen voltage for the driver tube and both final tube.
Arnie, measure the DC voltage on the Rectifier Unit's "210A" and "210B" terminals.

If you measure "0VDC" on 210A but +265VDC on 210B then check Rectifier Unit resistor "R6", a 470 ohm 1/2 watt resistor, it may be open which if it is open, would result in loss of screen voltage to the RF Unit's driver tube and both final tubes on the Final Unit!!!
Discussing how good the receiver works and that the 820 did transmit before is, at this point, of no interest!! You should be concerned ONLY about the loss of driver and final tube screen voltage. So measure the Rectifier Unit's "210A" AND "210B" terminal voltages ONLY then report back what you find.

Hola amigo Mike !

You are absolutely right ! Using a big magnifying glass it was possible to follow the circuit, leading to an analysis that coincides with yours... Open resistor.

My problem now, is how to reach the 470 ohm 1/2 Watt resistor on the Rectifier Unit. Using a very low watt rating resistor makes it act as a protection... if there is a short circuit at the screens or the driver, it will simply open up ....

When I finish working, will go ahead and try to find the R6 resistor's location...measure it and if needed will replace it .

The freq. was off when I hooked up the freq.counter as you suggested.. Then I thought about the old days on crystals.. Sometimes you can get them hot and hey will go back to the original frequency.. All I did was to reseat the connection of he crystal and it all fell into place.. Tks to you and all the group of all the help that is found here. 73. Bob/N4VNL

Bob Royston

Arnie,

Resistor R6 on the Rectifier board is NOT used as a "protector" or a "Fuse". Resistors make horrible fuses!!!

Rectifier Unit's 470 ohm R6 resistor can be found by studying page 68 in the TS-820 service manual. Page 68 shows the Rectifier Unit's "Xray" PC board FOIL side view.

Replacing R6 with a new 470 ohm 1/2 watt resistor should be done ONLY after you have determined what caused R6 to fail and have fixed/repaired the cause of R6's failure.

OK Mike:

It appears that a short circuit developed inside one of the 6146's ,
causing the arc over.

Will work on the rig tomorrow , but have already replaced the two 6146's...

Also will check the 22 mfd electrolytic with the ESR meter, and check
the screen grid bypass capacitors...

Thanks a lot for the guidance on the repair job !!!

73 and DX

The 470 ohm resistors are NOT for protection ie fusing and they NOT 1/2 watt. If you have 1/2 watt resistors installed they have been changed out. They are 2 watt metal film. If they fail usually one of two reasons why: 1. Radio has been hot rodded (common mod to increase final tube SG voltage)
2. Final tube arc over event. Most common arc over is from anode to cathode, but from time to time can have an arc over to the screen grids and rarely to the control grids.

This filter config is a very common CRC or Pi filter. Perhaps too hard for you to see this as the two caps are not physically on the HV Rect board adjacent to each side of the 470 ohm series resistor? They are physically too large to be located there and are remotely located.

The first 22uf cap is what we would call the "Input" cap or the "Reservoir" cap. It does the yeomans job of smoothing out the 60hz half wave rectification pulses from D6. The 470 ohm resistor and the 2nd 22uf cap form a low pass filter and that cap is commonly referred to as the "Smoothing" cap. The RC combo reduces the millivolt ripple level from the Reservoir cap.

If you calculate the Xc of the 22uf cap you will see it is approx 120 ohms at 60hz. Now with 470 ohm resistor and 120 ohm Xc you have approx a 4:1 divider. So the mv ripple is reduced by a factor of 4.

In the old days radio mfg would have installed something like a 10 henry choke instead of the 470 ohm resistor. KW used the resistor as a cost and space saving measure. Chokes are big and heavy and expensive. If they had installed a 10 hy choke the XL would have been approx 3800 ohms. Now 3800Xl/120Xc = 32:1 ratio so the mv ripple would be reduced by factor of 32. So the CLC Pi Filter is much improved over the CRC Pi filter.

CRC filters are most commonly used where there is relatively low current draw like a bias supply and in our hybrids for the SG supply. Not the best choice as regulation isnt very good.

Strongly suggest that you do not install 1/2 watt resistors for either of the two 470 ohm Pi Filter resistors. There is approx 20ma Final tube SG current, 4 ma Driver tube SG current and couple of ma of standing current due to divider resistors for the Driver tube screen and for the STB (side tone bias). Total max current that either the 300 supply 470 ohm resistor sees or the 210 supply 470 ohm resistor sees is no more than 30ma and more typically around 25ma. You can easily confirm that by measuring the IR drop across each resistor and calculating the current. At 30ma and nominal 470 ohms would disspate approx 0.42 watts. Could get by with a 1 watt resistor, but I would go back with a factory 2 watt metal film.

If you do check the IR drop across both 470 ohm resistors make sure you do it at 100 watts at approx 200ma Ip into 50 ohm dummy load. If you see much more that 12vdc dropped across either resistor I would look at the above two mentioned dividers. The 3.9k and 82K Driver tube divider on the RF board is almost always bad. This of course is based on both Pi-filter resistors being close to 470 ohms which your should measure with rig down powered

and caps discharged. Can be measured in place without lifting a lead. Once you have measured the resistance values and the associated IR drops easy to calculate the dissipation they see.

If you pressed on a Het Osc Xtal and got it on freq then you have bad solder connections. The Het Osc xtals are not in sockets. The xtals do not have pins they have leads.

Also, it is not a good idea to adjust the Het Osc using the RCA jack and a Freq counter.

Always adjust by measuring the RF voltage at TP-3 on the RF board and adjust the tank coil slug for peak in voltage and then back it off approx 1 dB on the slow side of the response curve. If you adjust tank coil slug for exactly 12.395mhz for example you may be exactly on the peak or slightly to the fast side of the response curve and could end up with Het Osc failing to start reliably each time. So for example if you measured 600mv rms at TP-3 by peaking the Xtal tank coil you would then adjust the slug (counter clockwise) for a reading of approx 535mv.

Arnie,

I think you need to step back for a minute and pause as it appears you are chasing symptoms and not causes across your radio. Given that your radio was working before you started having failures, the symptoms as a whole indicate aging issues -- most likely as I mentioned before, the electrolytics. All of the failures you have seen so far are highly consistent with electrolytics failing across your radio due to it not being used for so long and vintage (IMHO).

Before you proceed further, I'd recommend you replace the larger electrolytics wholesale across your rig -- the 22uf caps Terry K9TW mentions are highly suspect, to me -- and a standard capacitance meter ** WILL NOT READ CORRECTLY ** because those electrolytics will only fail under HV (high voltage) conditions. If you have a high voltage capacitor tester (unlikely) you might be able to see they have failed.. but a normal capacitance meter will read fine until high voltage is applied. With 100% tube rigs, you see the failure of those electrolytics as you turn up supply voltage on a variac -- they might work at 50V supply, but fail at 120V.

I personally would replace all of the electrolytics related to the tube power supply and any larger electrolytics being used for 12V regulation/etc. as a first try -- there are only a few. You *MUST* get the high voltage capacitors here -- i.e. I think most are spec'd at 450V last time I checked.

Easy to look at the rupture vents on the 300 and 210 supply dual can caps and almost always will be swollen and sometimes cracked as well. I always replace on all 820s that cross the bench.

I dont bother to measure capacitance with LCR bridge as it is pretty meaning less unless cap would be open or shorted. Also, they often ESR within range, but they are 30 years old so silly not to replace. I replace with dual can 20uf 500wvdc Richy Golds from Canadian supplier which are a bit pricey, but like to go back close to original config. Some folks replace with 4 axial or radial lead caps which isnt as nice looking, but is functional.

I also would look at the two 900vdc caps rupture vents. Again very common to have swollen and/or cracked vents. Even if they ESR within range I replace under the preventive maintenance and life extension umbrella.

I also ESR the two -C supply caps and rarely find them bad, but again might want to consider replacing as loss here can result in the destruction of the Final tubes due to thermal runaway the moment the heater switch is turned on with no cutoff bias on the control grids. This can happen also if you disturb molex connector RF-3 on the RF board.

I would be extremely careful and give some considered thought to complete electrolytic replacements on the PC boards. It sounds intuitive, but it comes with risks. Get more than my share of requests for help from owners who do that and the radio no longer works.

The molex connector crimp terminal connectors are a very big problem and plug and replug can result in high Z connections and/or intermittent connections. The crimp on the lead wire can be bad especially if you have a rig wired with solid lead wire instead of stranded wire, the spring temper wedge on end of the crimp has lost its temper and makes poor contact, and/or the wedge has broken off and is floating around inside the molex connector plug body. All problems that you can induce or exacerbate during a total recap not to mention problems with solder pads and traces.

The high energy caps are pretty easy and no brainers. I wouldnt be too quick to change any others unless troubleshooting to the component level indicates the electrolytic cap is the root cause.

Terry,

You're right, Rectifier Unit's R6 470 ohm is not 1/2 watt but as you pointed out, R6 is 2 watt. I mistakenly read the resistor just above it on the Rectifier Unit parts lists which is 410K 1/2 watt, my mistake. Need new glasses!!

Mike:

I was addressing the Professor. I thought he mentioned that the installed ones were 1/2 watt. I didnt want him replacing them with 1/2 watt units. I didnt notice that you had called them out.

Having done so many units now I know many of the component values by memory and can see them in my sleep or my dreams or I mean my night mares!

It is interesting how many people lurk in the shadows and read this stuff and then will send me something off list. Got one today asking if a 10hy choke that has an Xl of 3800 ohms at 60 hz is so good why didnt KW engineers just spec a 3.9k ohm resistor instead of the 470 ohm resistor in this Pi-filter. Still some thought that these 470 ohms are some kind of protection device. Hard to debunk some of this thinking. Still a good question and an easy answer. 3.9k ohm of resistance represents significant DC heat loss. The 10hy choke probably has a DC ohmic value under one ohm so has very little IR drop. 3.9k resistor would drop the output voltage and waste lot of power in the form of heat. I didnt have time to explain difference between 3900 dc ohms and 3900 ohms of inductive reactance. I referred the chap to ARRL handbook to read about a choke and what Xl is and the opposition that 3900 ohms of Xl presents to the 60hz ripple.

I know you and I can remember the days when there would be great big chassis with a big plate transformer, maybe a big filament transformer, a big modulator transformer, and a couple or more big power supply filter chokes. A lot of iron. Part of reason it took a strong back and a strong bench to carry a Heath Apache or a Johnson Viking! When you look at size of components today maybe none of it was really required. Of course we didnt have computers and calculators so we werent able to calculate the margins so close. Probably had 10x factors figured in. I think we called it quality.

I think if we look at most of the ARRL handbooks would see CLC Pi filters and a few choke input filters in the chapter on Power Supplies. Not sure they even show a CRC filter? For those interested in how they work Google is probably best source.

I think quite a few of the Hybrid owners cant make the connection to the filter caps and these two 470 ohm resistors due to the physical mounting locations and how drawn on the schematics. Same with the 530/830 rigs with the 300 supply resistor mounted on the IF board with the all 4 caps and the 210 resistor on the HV rectifier board. The only one that looks like a CRC or Pi-filter is the 300 supply drawn on the 830 schematic of the IF board.

Topic: 54481 Message: 56100

Welcome to the Yahoo Kenwood TS-520_820_530_830 Amateur Radio Group. This group is comprised of members who's interest is in maintaining and operating the Kenwood TS-520, TS-820, TS-530, TS-830, TS-510, TS-511, T-599/R599 and R820 Hybrid transceivers, transmitter and receivers. In addition, the group supports discussions covering the associated Kenwood accessories such as the VFO-520, VFO-820, VFO-230, and VFO-240 remote VFOs, the Kenwood antenna tuners, and the various Kenwood desk and hand microphones.

This is a restricted group requiring membership approval prior to receiving and posting messages to the group. To join the group simply complete the Yahoo Kenwood TS-520_820_530_830 Group's application process by clicking on the “+ Join Group” icon on the group's homepage. Select the desired method of receiving messages by clicking the appropriate radio button, then provide a brief description about yourself to include: your first name, your Amateur Radio call sign, your interest in the Kenwood hybrid radio, and the model of Kenwood hybrid you own, operate, or in the process of purchasing in the text box provided. If you are not a licensed Amateur Radio operator, no problem, simply complete the application process and provide the same information less the Amateur Radio call sign. Once you have completed the text, click the Join Group icon. Your application will be reviewed and approved by a group co-owner or Moderator. If you leave the application text box blank, your application for membership will be rejected. Simply reapply and provide the information requested and resubmit your application for membership.

New members are placed on a "Moderate" status. This means that any message a new member posts to the group must be approved by a group co-owner or Moderator before it appears on the group server for all members to see. The length of time a new member remains in a "Moderate message status" is determined by the members ability to adhere to, and follow the group's policies. The faster the new member(s) can prove they are adhering to, and following the group's policies, the quicker the new member's status will be changed to “Allowed”.

The “Allowed” status means the member can submit/post their messages without group co-owner or Moderator's approval. A member who's message status is set to “Allowed” may have their message status changed to "Moderate" if it is deemed necessary by a group co-owner or Moderator for one of the following reasons:

1. Failure to follow the group's policies after being informed by a group co-owner or Moderator
2. Knowingly violate any of the group's policies
3. Any improper behavior by the member that is deemed inappropriate by a group co-owner or Moderator

The group is moderated by both group co-owners and group Moderators. While we would like to have a group co-owner and/or Moderator present 24/7, that is not possible, as group co-owners and Moderators have a life too. Therefore, there will be times when a group co-owner and/or a moderator will not be present. This will affect the time a moderated member's messages may take to get approved/rejected. This occurs most often during major holidays Also, the group's server is not maintained by the group co-owner(s) or Moderators.

Therefore, when Yahoo has problems affecting Yahoo Groups, ALL members will simply have to wait for Yahoo to fix the problem. Group co-owners and Moderators also do not have any control over how the group's server handles attachments to messages or how message search results are provided.

Page 1

As stated above, this group has a set of policies that all members must agree to and abide by. If any member, new or old, that feels they cannot accept the group's policies, that member is free to terminate their membership at any time without notifying the group co-owners and/or Moderators.

Group's Policies:

1. Profanity of any type, regardless of the word and/or phrase(s) used in a message, is not allowed. This includes the use of abbreviation to improper words, use of symbols to substitute for letters, etc. In short, the use of profanity is NOT ALLOWED, PERIOD!!! The quickest way to get banned from this group is to use profanity!!!

2. Disrespect/Flaming any member regardless of the reason, is not allowed.

3. Taking over a thread by a member that changes the threads original subject and content, is not allowed.

4. Messages that contain as part of the message text, discussions of a member's private life are not allowed. Responses to messages are to pertain to the original message subject.

5. Long discussions that are products of an original messages are not allowed. If there are 2 or 3 members who wish to discuss a subject in more detail and at great lengths should take their discussions off the group and continue their discussions using private email addresses.

6. MESSAGES THAT DO NOT CONTAIN ACCEPTABLE MESSAGE SIGNATURES, WILL BE SUMMARILY REJECTED! It takes less than 5 seconds to ensure your message contains an acceptable message signature. There is no excuse for not adding a message signature to your messages. Political or religious signatures/statements are not permitted.

The following are examples of the ONLY acceptable message signatures:

Licensed Amateur Radio members:

Example:
“73s
John WA1ABC”

Non-licensed members

Example:

73s
Mary

If a member does not wish to include their Amateur Radio call sign in their signature, then simply use their first/given/Christian name ONLY, same as non-licensed members.

Each message signature must be positioned at the bottom of the message text and separated by at least one line.

For example:

Hi John,

Yes capacitor C25 is the right cap you should be checking. For details, review the schematic.

73s
Bill

Screen names such as JLH524 or MWPO125 are not acceptable message signatures. Screen names are acceptable ONLY when used as part of the member's email address.

The member's email address is not an acceptable message signature, regardless whether the member's name appears in the email address or not.

A member's “initials” are not acceptable as a messages signature.

A member may add up to 2 additional lines to their message signature. The additional 2 lines may contain a link to the member's website and a link to the member's Amateur Radio club etc. The addition of 3 or more lines to the message signature, listing the many different clubs the member belongs to, the positions they hold within the respective club(s), their professional position within the company the member works for, and other information is considered excessive and not allowed. The following is an example of an acceptable message signature containing two additional line:

73
Mike-w5rkl
www.w5rkl.com
Yahoo Kenwood TS-520_820_530_830 Moderator (Mike-w5rkl is no longer a Moderator, but used as an example--tnx)

In the past there have been members who state our group policies are too strict. We maintain strict group policies for 2 simple reasons:

1. To maintain good order and discipline in the group.
2. Provide a friendly group where all members are treated equally and an environment free of improper behavior

73
Yahoo Kenwood TS-520_820_530_830 Hybrid Group Co-owners and Moderators.

56101. File - Rules, For Sale or Want to buy Posts

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-12-01 12:38:38 UTC
From: TS-520_820_530_830@yahoogroups.com
Topic: 54620 Message: 56101

Rules pertaining to Occasional For Sale and Want to Buy Posts.

Members of the TS-520_820_530_830 Yahoo Group who have been members for at least 30 days may place " for sale" posts no more frequently than two in any 30 day period." Want to buy" posts are permitted immediately upon membership and are limited to 2 in any 30 day period.

For sale posts are limited to the sale of TS-510, 515, 520, 820, 530, 830, and the 599 series twins, as well as Kenwood accessories intended for use with these radios.
Also, group members may post "service equipment" for sale. This may include, but are not limited to: vtvms, various signal generators, and other testing/service equipment. Posts must include: the make and model of the item for sale, as well as an accurate description of its condition, and the asking price.

When the item is sold, please make a short post to that effect.

Replies and discussions regarding these posts must be taken off of this group either by direct e-mail to the seller or as directed by the seller.

Buyers and sellers are on their own. The TS-520_820_530_830 Yahoo Group, its owners, co-owners, moderators, or members other than the seller, hold no responsibility for the accuracy of the posts or the credibility of the seller or buyer.

We do not expect that members of this group will misrepresent, or in any way cheat other members. At the co-owners(s)/moderators discretion, we may choose to ban any member from making further for sale posts, or ban the member from this group entirely if we believe their posts or transactions are not of the utmost integrity.

We ask that those who buy and sell equipment as a main business not post here. We will allow posts from members who occasionally restore and sell equipment/accessories as stated above.

We expect our members to use discretion. If excessive traffic develops as a direct result of these postings, they may have to be discontinued.

Walter Breining, N9WB
Joseph T Stiles, WB7UQU

Victor:

I have never done it on a TS-820.

I have seen a TS520 with one Final tube and I have some info on converting it on my website www dot k9tw dot com. Look under the How to Guide page.

I would guess that the mod is very similar if not exactly the same. Here is some of what I would expect you would find in your TS-820V:
1. The HV (Final tube B+ or anode supply) is presently wired in a full wave rectifier config and using the 400 tap on the transformer secondary. You will need to lift that and land on the 800 tap. You will need to add another HV filter cap, rf bypass cap, and bleeder/equalizing resistor.
2. Will have to remove the full wave bridge rectifier diode config on the HV board and rewire diodes as a voltage doubler.
3. Look for a 6.2 ohm sand power resistor in the Final tube filament string and remove it. Should be on the Final board. Will have to wire the two Finals tube filaments in series.
4. Will have to add another tube socket to the Final board.
5. Will have to add additional screen grid and cathode bypass caps.
6. Look for a 15pf cap on the existing Final tubes control grid to chassis ground and remove and discard. This cap limits and shunts the RF drive from the 12BY7A driver stage. Will also have to add a parasitic suppressor to Final board to supply bias and rf to the control grid of 2nd tube.
7. Look for a 12k to 18k series resistor in the Final tube Screen Grid supply. This reduces the SG to approx 160vdc. Remove and toss it. Need approx 260vdc on screen grids. It may be physically located on Final board in the PD2/PD1 path. Will have to add a 100 ohm Screen grid stopper resistor at the new tube socket.
8. Add another 10 ohm Cathode meter shunt resistor on Final board at the new tube socket.
9. Add another parasitic suppressor at the top of the RF Plate choke in the PA cage to supply the 2nd Final tube anode voltage.

After all changes made suggest you re-align the Driver stage and re-neutralize on 28.8mhz. Service manual will tell you 21.225 mhz, but better to do it on 10 meters as more propensity to take off on 10 due to lower Xc of inter-electrode capacitance and greater level of feedthru RF voltage from Plate to Control grid.

These are the things that come to mind. Again I have NOT made this conversion and this is not presented as a complete list or a 100% accurate list. It should give you an idea of the main items that you will need to address.

Study the schematic and just make the new as built config match the schematic.

Terry K9TW

Victor:

I may be mistaken about need to add another 10 ohm cathode resistor. It may already be there. Measure the cathode resistance and if 5 ohms your OK. If it measures 3.33 ohms then there is an additional 10 ohm resistor on Final board that will have to be removed. If total cathode resistance measures much above 5 ohms then replace any and all 10 ohm cathode resistors with two new 10 ohm cathode resistors. One at each tube. The higher the cathode resistance your plate current (Ip) will read false high making you think you are loading heavier than you really are. You are actually measuring cathode current which includes the screen grid current, but KW and owners all call it plate current.

As I recall the 520 I worked on did not have any of the disc ceramic caps, SG stopper resistors, cathode resistors etc inserted in the thru holes on the PC board around the space where the 2nd socket was not installed. Probably a cost saving measure. I think for that reason they did tack solder a 10 ohm resistor on the #1 solder pad where the 3.3k meter multiplier resistor is landed. Again this is from memory and at my age it fades and sometimes blanks out!

Ok, Terry. I red your article in your site and saved it. It looks a little bit complicated for me, but I will try. My TS-820V will be shipped on Sunday, and approx. in two weeks will be in my hands. Today, I bought in ebay.com second s2001a. I am looking forward to get it. I want to buy cw filter YG-88C, but did not find in ebay.com

Victor:

Your TS-820V will most likely be labeled as a TRIO TS820V on the front panel. Ideally it would be best if you could find the Trio Service Manual as it will have the schematic and x-ray view of the Final board. It will cover the TS-820X,V,D, and I believe also S model. Might be printed in Japanese?

Perhaps a member has one that they could copy for you?

With extreme care... following advice of Mike and others.... I found that a 470 ohm resistor that is connected to the plus side of the rectifier diode D5 is OPEN... At the other side of the 470 ohms resistor that to me looks like a standard carbon 1 Watt unit, there is a wire that checks zero ohms to the 33 mfd electrolytic located close to the screen grid switch... Checking from there, I also see zero ohms to a terminal marked SG on the PC board that is the support for the 6146's finals.

Then checking from the SG terminal to ground A DEAD SHORT CIRCUIT !!!

I then suspected a shorted 6146 tube that arced over and is in a short circuit to the cathode....

Removed the two 6146's and the short circuit condition was no more seen...

Tested the two 6146's and one had a dead short from pin 3 to pins 1 and 8 of the tube...

The resistors at the X 43-1110- look like small size 1 Watt and with the Fluke model 75 Digital Multimeter I read:

56000 ohms

another 56000 ohms

12000 ohms

and 100000 ohms.

The terminal post marked PLUS 210 checks Ok continuity to the SG point at the board of the 6146's cage and also checks OK to the 33 mfd electrolytic located near the screen grid ON - OFF switch...

Please advice if you think that I can replace the damaged 470 resistor with a 430 ohms 1 Watt resistor that is larger in size than the damaged 470 ohms resistor...

I plan to run the test by using a VARIAC and measure how the screen grid circuit behaves, in order to avoid further damage in case something else is wrong....

Thanks for the help...

73 and DX

Arnie,

The 470 ohm R6 resistor on the Rectifier board is a "2 watt" resistor
NOT a "1 watt" resistor!!!! If R6 on the Rectifier board is found to be
open then replace Rectifier board's R6 with a 470 ohm "2 watt" resistor!!!!

6146A/B/W pins
Pin 1 is the one side of the Cathode
Pin 2 is one side of the filament
Pin 3 is the Screen
Pin 4 is the Beam Forming element connected both INTERNALLY in the tube
and EXTERNALLY at the tube socket to pin 1, the Cathode
Pin 5 is the Grid
Pin 6 is the other side of the Cathode
Pin 7 is the other side of the filament
Pin 8 is Ground (base of the tube's outer ring. Pin 8 on the socket is
wired directly to ground)

You can download the 6146A/B data sheets from my website by clicking the
following links:

6146A:
http://w5rkl.com/wp-content/uploads/2014/04/6146A-GE.pdf

6146B:

Arnie:

Did you mean D6 and its Pi-filter resistor R6 and not D5 and R5?

If D5 is not a typo and R5 is the open 470 ohm resistor you are talking about the 300 supply which is the nominal 340vdc anode supply for the Driver tube and has nothing to do with Final Tube SG voltage. If R5 is open then you will have no RF drive to the Finals.

One exception would be if someone has "hot rodded" your TS820S by jumpering the 300 supply to your Final tube Screen grids to get more output power. A very dumb mod.

Using a 430 ohm resistor is no problem, but generally you cannot go by physical size as an indicator of wattage rating unless it would be an order of magnitude difference.

Hola amigos: The open circuit 470 ohms resistor is connected to the D6 diode plus side (cathode) and goes to another binding post that gives a reading of very low ohms to the 33 mfd capacitor near the screen grid switch... that is the one that has the brown wires....

So next step is to solder the 430 ohms 2 Watt new resistor in place of the damaged open circuit 470 ohms... The physical size of the 470 ohms resistor looks to me like a classic 1 Watt dissipation resistor... My 2Watts rated resistor are of a larger physical size.

Have the VARIAC connected to the rig, and will start at a low AC voltage while measuring the plus 210 terminal and the voltage at the 33 mfd electrolytic that is next to the screen grid switch...

As my dad used to say when taking off with the PBY Catalina fully loaded with antisubmarine capability.... V2 speed, and fingers crossed.... Airborne !!!!

Topic: 56120 Message: 56120

Dear amigos: After finding the open 470 ohms 2 Watt resistor and
putting a new one, the screen grid voltage to the 6146s went to normal...

So the short circuited 6146 was the cause of that problem.

Then something really bad happened again and the front panel meter goes
to the very end on several of its positions, except , it measures the
800 volts OK, and it measures the Ip idling current...

Now there is very little RF output , but the PI network tunes...
although the carrier control at maximum produces a very little upward
plate current above the 60 milliamps idling controlled by the bias control.

I have not been able to print the circuit diagrams... and so do not have
an idea of what may be causing the front panel meter to peg to the end
on all of the MODE switch positions while on the receive mode.... The
radio does pick up the marker generator...

When the send switch is activated, the meter reads the 800 volts... it
puts the middle somewhere but not at the end of the travel to the right
when the COMP is selected, then it measures RF output, but now very
little output, but it does peak and tunes with the PI network and the
drive control ...

When USB or LSB is selected , the plate current moves upward but very
little and the RF output also moves upward with audio from the MC50
microphone, but again very little power output....

The screens of the 6146's are receiving plus 240 volts...

Now the damage seems to be somewhere along the RF chain....

Any ideas or suggestions where to look now.... ?

73 and DX

Arnie Coro CO2KK

P.S. The screen grid switch works OK, because the plate current drops to
zero when the screen grid switch in the OFF position.

Also checked the transverter switch... just in case... and it seems to be OK

56124. RE: TS820S Front panel meter pegging the needle on all MODE switch position on RX

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-12-02 20:44:25 UTC
From: Prof. Arnaldo Coro Antich
Topic: 56124 Message: 56124

Still battling with the old Kenwood TS820S... after what appeared to be a more or less happy comeback... suddenly another arcover somewhere (no trace of the location to be found by visual inspection) and then two things happen.

1. The front panel multimeter is pegging the needle to the end during the receive function , at any of the MODE switch positions...

2. The same meter, when the SEND switch is activated, does measure the plus 800 volts, shows a middle scale needle reading on the Compressor position... The RF output is now very low... (but tunes to maximum low reading when tweaking the PI network and the drive control)

On the CW position , output is very low, like lack of RF drive...

Connecting the microphone, it also transmits but again very low power, although the transmit audio quality as heard on the MONITOR switch ON position is OK....

The 6146's grid bias voltage is at minus 53 volts...

The 6146's screen is at 240 volts

The 6146's plate voltage as read on the front panel meter is at 800 volts...

AC Power line voltage is 115 to 120 volts

Any suggestions will be most appreciated !!!

Peter,

I don't know where you are getting "455Khz" 3395C filter. The TS-520 does not have an IF frequency of 455Khz.

The TS-520 3395Khz filter is not compatible with the TS-830 8Mhz IF. You will have to purchase the appropriate CW filter for your TS-830.

I recommend reading up on the TS-830 specifications in the TS520 and TS-830 operator and service manual's "Circuit Description" and "Specification" pages. You will find the two transceiver's have entirely different IF frequency and none of the filters are interchangeable between the 2 transceivers.

Victor,
You can....but I recommend using the 6146B or the 6146W. There is a file in the "files" section of the group home page, regarding the 6146 series of tubes. It's written well and has good information

No change necessary but you may have to get neutralized. See if the dipping point and maximum power output occurs at the same point, then it is not necessary to re-neutralized.Good luck.K6hm

I'll be the first to jump in, as long as they are 6146B or W's and you might have to neutralize them. Not a big deal just don't use A's

Victor,

You should never use a 6146 in a Kenwood Hybrid. The correct replacement tubes for the S2001 are the 6146B, or 6146W. The W is a ruggedized version of the 6146B. Mike, W5RKL has the tube data sheets on his website, http://w5rkl.com/manuals/

Scroll down to the bottom where the data sheets for the 6146A, and 6146B is.

Victor:

Yes you can run 6146, 6146A, and S2001 final tubes. Seen my share in all the KW hybrid models. They can be loaded to 100 watts output and will neutralize just fine as the inter-electrode capacitance is nearly identical between manufacturers.

However, the reason that it should not be recommended to use them is due to fact that they have 25 watts plate dissipation instead of the higher 35 watts that the S2001A, 6146B, and later production 6146W have.

With the introduction of the TS820S KW replaced the TS520 S2001 tubes with the new S2001A tubes. This was primarily to support the FSK mode and the RF processor function. These features increased the Final Tube duty cycle requiring more plate dissipation.

What allows you to run the 25 watt dissipation tubes is reasonably short loading times so you dont exceed short term dissipation and the fact that SSB and CW modes are relatively low duty cycle modes. Depending on your voice characteristics, if routinely running RF processor without a lot of compression (greater than 10dB), and moderate keying speeds you should not exceed the 25 watts dissipation and should never see any anode color.

Where the problem really comes in is running digital modes and more so than with the 35 watt rated tubes. You must reduce loading to ensure never see any anode color.

So if you have a hard time finding S2001A or 6146B, or 6146W in your area of the world and can find 6146, 6146A, or S2001 go ahead and install a pair and neutralize. The service manual states to neutralize on 15 meters. I would neutralize at 28.8mhz where the Xc of the inter-electrode capacitance is lowest allowing the most RF voltage feedthru and thus greater propensity to take off. If you never operate on 10 meters then go ahead and neutralize on 15 meters around 21.2mhz.

It is best not to mix any of the 25 watt dissipation tubes with a 35 watt dissipation tube. For example dont mix a 6146 with a S2001A. Since we have one bias supply cannot assure load will split equally between the two tubes.

Lastly, when you get your new TS820V remove the fuse from its holder and make sure it is a 6A fast blow fuse. Never install automotive fuses or time delay like MDL units.

Terry K9TW

56138. TC1 10MHz PLL trimmer

Yahoo group: TS-520_820_530_830 (2015 — 2016)

From: rrmvargo@...
Topic: 56138 Message: 56138

After finally finding the fault on the display board (replaced bad IC Q14), I checked the LO frequency on my TS-830S. The frequency was a little low so I tried to tweek TC1 on the PLL board to get to 10MHz. Well try as I might, I could not get it right on 10MHz. It seems there is a hot/cold spot at the perfect spot for 10MHz and just the tiniest of movement would make the frequency change a bunch. Plus the LO was pretty unstable near this location also, causing a lot of VFO drift. Maybe not a good idea, but I gave TC1 a shot of contact cleaner & worked it back & forth. The hot/cold spot was unaffected. When I would off tune TC1, I could get the LO to be stable, a few Hz up & down and the VFO was stable if not accurate.

So I am thinking I need to replace TC1 (50pF) or tack on a 10pF NP0 to get it into a stable & accurate place.

Anyone ever replace TC1 & where did you get a high quality replacement that fits? Or any other comments/suggestions?

Thanx – Bob W8RMV

NEVER use a pair of 6146 or 6146A in KW hybrids? No that's not true.

A couple of differences between the 6146/6146A and 6146B/8298 are:

6146/6146A
Plate to Grid #1 inter-electrode capacitance is .24pf

6146B/8298A
Plate to Grid #1 inter-electrode capacitance is .22pf

The other inter-electrode capacitance values between the tubes are the same.

6146/6146A plate dissipation rating is 25 watts

6146B plate dissipation rating is 35 watts

The following links will download the GE and RCA manufacturer's data
sheets for the 6146/6146A and 6146B/8298A.

6146/6146A
http://w5rkl.com/wp-content/uploads/2014/04/6146A-GE.pdf

6146B
http://w5rkl.com/wp-content/uploads/2014/04/6146B-RCA.pdf

There is a "Pulse" rated 6146A, the 6293.

http://w5rkl.com/wp-content/uploads/2014/04/6293-pulse-rated-6146A.pdf

The 6293 has the same inter-electrode capacitance values as the 6146A.

Simply switching to a pair of 6293s will NOT result in any increase in
power output!! The same applies when switching from a pair of 6146/6146A
to a pair of 6146B/8298 will not result in any increase in power output.

56143. Hybrid Net Update (December 4, 2016)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-12-05 13:17:25 UTC
From: Mark Gilger
Topic: 56143 Message: 56143

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by Stu, K4BOV . There
were 9 stations checking in under fair band conditions.

We had the following number of radios checking in.

0 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running TS-515
0 running 599 twins
0 running TS-900

He was running a Swan 350 .

The Sunday net was run by me, WB0IQK. There were
18 stations checking in FAIR band conditions.

We had the following number of radios checking in.

2 running TS-520(x)
3 running TS-530(x)
1 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830S + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 ☐ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins
Nov. 2015 ☐ Oct 2016 Saturdays total 807 check-ins, Sunday total 628 check-ins

November 2016, Saturday net total = 80, Sunday total = 68
December 2016, Saturday net total = 9 , Sunday total = 18 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:

Hi Jan:

Why dont you email Merit Arnold W6NQ at his RF Parts email address and ask him why he has that note. I have done that and would be interested in what he tells you.

Suggest that you may have to send a follow up email and include verbiage similar to this:
1 Are the returns you get limited to KW Hybrid owners?
2.Why do they return them ie outright failure shortly after power on, have trouble neutralizing, other?
3. Do people who own rigs like Heathkit buy them and not return them? If so, what does he attribute to that?
4. If they run in a Heathkit why wouldnt they run in a TS520S?
5. Is it true that GE had a bad production run of the 6146W tubes? If so, shouldnt most if not all have been purged by now? I cant imagine Merit knowingly selling GE 6146W tubes from a bad production run that would lite up like a gas VR tube when powered!

I am sure you can think of other questions. There are so many Opinions, Beliefs. Folklore, Myths on this subject. I am afraid Facts are in the minority. I dont know anything about problems with 6146 neutralization problems as it has been reported related to Heath, Collins, and Motorola radios.

What I can tell you is that I do see GE 6146W and of course GE 6146B tubes in all the KW Hybrids I service and I have never had a problem neutralizing either tube. Also, the GE6146W tubes DC hi-pot fine and make good power. Of course dont see as many Ws as I do Bs. Problem I see with both GE tubes is the glue that bonds the anode caps to the glass is almost always degraded and lost the bond to the glass envelope and if not careful can twist off the tube plate cap when trying to remove the tubes. When doing that you can break off the plate lead where it exits the glass or even break the glass at that point and of course tube is ruined. Also, the shield ring is commonly loose, but doesnt impact performance.

Mike I apologize for butting in. Wanted to make sure Jan sent a note to Merit and to report back what his response was as to why he says "not for Kenwoods".

Last thing. I do not buy the GE6146Ws from Merit. I always buy his NOS JAN ECG/Philips 6146W tubes for my radios and install in all customers radios that require new finals. A bit pricey, but never got a bad one. If Merit could no longer supply the ECG/Philips 6146Ws I would buy a pair of his NOS GE 6146Ws so that I could evaluate them for myself.

I do get quite a few comments from owners that say they had trouble neutralizing just about any of the 6146 tubes, but I get the sense that they do not fully understand the What, Why, and How and the fact that it is not as critical as they are led to believe. I do not neutralize around 21.3mhz. I neutralize all KW hybrids at 28.8mhz.

In the old days when we may not have had required test gear or it wasnt easy or convenient to lift the SG lead to allow "cold" neutralization we would neutralize by trying to match max RF out to min plate current. I lot of repeat key down time could be required and often got it just "good enough" and in practice left it a little to either the inductive side or

capacitive side of resonance.

Jimmy WB2KNR if you are reading this I believe you returned a set of GE Finals? If so, were they NOS JAN GE6146Ws and why did you return them?

Jan,

I cannot speak for RF Parts, only RF Parts can tell you why they don't recommend using 6146Ws in Kenwood radios. You might write them and ask why they don't recommend their 6146Ws for use in Kenwood radios??

There have been discussions on various ham forums and websites concerning Chinese 6146Ws that appear to fail. Are the Chinese 6146Ws built to 6146A specifications which is what the first "W" 6146 in the mid 60s were or are they being passed off as 6146W equivalent to the 6146B? I don't know because I do my best NOT to purchase Chinese 6146 tubes. I buy all my 6146 tubes from vacuumtubes.net and I've never experienced a bad tube from them whether I use them in Heathkit or Kenwood transmitters and transceivers.

I believe the 6146W-GE/JAN were patterned after the 6146A and as such, have a plate dissipation of about 25 watts. The 6146W-ECG/Philips were patterned after the 6146B and as such, have a plate dissipation of about 35 watts. There is some minor interelectrode capacitance differences between the two varieties which might impact operation above 20 MHz. The 6146W-ECG/Philips is more closely related to the original S-2001A and the 6146B. The 6146W-GE probably could be used, HOWEVER, since the plate dissipation is lower, you would have to tune the transmitter to a lower value of maximum plate current. For the difference in price, for rigs that originally used S-2001A's or the 6146B's , I would recommend purchasing the 6146W-ECG/Philips or branded 6146B's. RF Parts should be able to give you the real answer, since my statements are taken from memory although I've used the ECG/Philips tubes and they work fine.

The date code on the "6146W" tubes determines whether it's a 6146A/8298 or 6146B/8298A.

The original 6146 and 6146A are the exact same tube except for a rugged filament in the "A". The early Military 6146W was equal to a 6146A/8298.

From what I have read about the 6146W tubes, changes were made around the mid 60s to the "6146W" to the new 6146B/8298A specifications but the labels on the tubes remained "6146W". This, from my reading about the tubes, is where the date codes determine whether a "W" is a 6146A/8298 or a 6146B/8298A. I do not know how to decode the date codes on the glass envelope, maybe there are members who can decode the date codes.

I have no idea whether RF Parts has the earlier "6146W" equivalent to the 6146A/8298 or not. I can only say I have not had problems with 6146/6146A/8298 or 6146B/8298A or 6146Ws.

If you do not feel comfortable using a pair of "6146Ws" then don't use them, simply purchase 6146B/8298A instead.

Hi guys

I can say that I have purchased both from RF parts. The non GE 6146w failed. Yet all the GE Jan 6146w nos have been perfect as Terry stated.
You get what you pay for.

RF parts have always been good to me, so if they say not for kW, they are giving good advice

Saying this I only buy emaic 3500z tubes for amps, yes expensive, but cheaper than a transformer and labour.

I look at it by advice from people who have experience, either accept or don't. If it fails because of failing to heed good advice, only blame oneself. I learnt the hard way many many moons ago

Good morning to all.

Please let me chime in on the GE 6146W discussion.

Here is what I remember hearing way back.

Pairs of 6146B type tubes were used a lot in commercial mobile equipment.

Apparently, GE changed the filament characteristics so that a pair of these tubes, with the filaments in series, would be best at 14.4 volts DC. That comes out to 7.2 volts each tube.

If this same tube were to be run at 6.3 volts, the cathodes would be a bit on the cold side, and the tube didn't perform well in that condition.

For some reason, GE called this tube a 6146W. An oversight by some not very bright genius.

It wasn't long before hams discovered this problem, and the "stay away from all GE 6146B type tubes" was often heard back in 80's.

Well, that is what I remember on this subject.

Merry Christmas and Happy Holidays to one and all,

Bruce N4JHY

All of the NOS JAN ECG/Philips 6146W tubes that I have bought from Merit Arnold have come in white military boxes and dated 6/86 and most recently the boxes were dated 10/86. Just looked at 3 sets and the date code on the glass envelopes is 8652 with a 3 letter code like AAW. I dont recall ever receiving a tube that wasnt dated in 1986.

I do not know for certain if 1986 tubes are 35 watt plate dissipation, but pretty confident that they are based on dc static testing and having run them in both of my TS830S rigs for 8 to 10 years at 100 watts loading. No signs of emission falling off and no shiny silver spots on the black plate surfaces or sharp metal folds.

Static testing is not a recommended routine test for the average owner. I have performed this testing on my own radios running both RCA 6146B and ECG/Philips 6146W tubes and do not perform it on customers radios. I do DC hi-pot all customers Finals and check emission simply by loading to approx 200ma to confirm can produce 100 watts output.

I performed static DC testing (no rf drive) by running the operating bias pot voltage down until the plate current is pegged full scale (350ma) while I watched the plates with the PA cage shield off and never once saw any color begin to show. Will hear the transformer complain and may hear the glass tinkle a bit and can smell the heat. Again, do not do this as a routine to assess your tubes cathode emission or plate dissipation.

I have never done this test on a GE 6146W tube. Maybe the next owner who sends me a hybrid with pair of GE 6146Ws will be the lucky winner!

I have had this rig and VFO since I acquired them from an SK's widow about 20 years ago. They are definitely new and according to the woman, her husband never put it on the air because he got sick and never used them. I opened the boxes only to inspect them and I have to admit, they are certainly new.

Now that I have had these for at least the last 20 years, I have no desire to turn them on or use them since I am afraid of a possible cap failure in the power supply and I'm approaching my late 60s.

So, I am going to put it on Ebay. My question is to the group, what do you guys think would be fair value for them?

Hi Victor,

Two tubes at 100 watts output, I would definitely have a fan on these tubes at this level.

Kenwood has their fans blowing out. This is to help stability of all the oscillators. Without a fan, besides the tubes not being very happy, the heat ingress into the radio would most certainly contribute to drift.

Yes, on a fan, blowing out.

Best to you, Bruce N4JHY

Doug,
You stated that you have "swapped out every component from the bad radio........" does this include the PD/VCO unit? You need to obtain Service Manual for the TS-820S and look at Pg 40 and also Pg 52 Section 5-2 "Adjustment of VCO." The VCO, voltage controlled oscillator, (X50-1330-00) is part of the PD/VCO unit(X60-1010-00) it is on the underside of the chassis. I believe the above info is applicable to the R820

Dear Victor,

You would want the air blowing out.

Here is why-

With the air blowing out, air is drawn into the radios cabinet in several places.

This air is a constant temperature air (your room temperature), and this constant temperature aids in the stability of the radios frequency.

If you were to blow air in, instead of out, the temperature of the air would be constantly changing, as you talk into (modulate) the radio/final tubes.

This changing air temperature, both up and down, depending how much you xmit, would tend to make the radio's oscillators less stable (drift)

Drift= BAD

Air out, stable temperature = GOOD.

Best luck my friend,

Bruce N4JHY on the coast of South Carolina

The DG-1 is very sensitive to input signal levels.

Measure the VCO (CVC) and Carrier (CCR) levels with the DG-1 in the good radio and adjust the levels in the bad radio to match. Carrier should be no greater than 50mv.

Also, check the 14vdc and 5vdc voltage inputs as well.

Today I was given a partially operational 830s (Gold Label). At least that's what it says under the VFO. Seems to rx ok, no tx of any kind anywhere. HV is there but no rf out, no plate current...zip.
Sadly this rig was previously owned by a reformed cb'er, not to knock them too much but that was the way of thinking with this fella. The plate choke is pretty smoked and looks like some nearby resistors got pretty warm as well. This is the rig I've been looking for quite some time. I've a 520se perfectly operational on the desk and two 820s's on the floor (partially operational--needs work) I suspect I may use one of the 820's for parts if necessary. Any starting advice from you experts would be greatly appreciated!

Forget the "Gold Label" tag; it means nothing.
The first issue of the 830 service manual showed the silver label with it's part number. Approx. a year later, the service manual was updated, and the gold label with its part number appeared. The gold label and part number were there for the rest of the life of the 830. In the sunset of the 830's life, CW filters were added to sweeten the sale to move out the remaining 830's from dealer's shelves and any remaining in Kenwood's inventory. QST and/or CQ ran ad's for 2 or 3 months touting this "special sale". The addition of the filters had nothing to do with the "gold" label.

Pete, wa2cwa

---In TS-520_820_530_830@yahoogroups.com, <wayne.bowyer@...> wrote :

Today I was given a partially operational 830s (Gold Label). At least that's what it says under the VFO. Seems to rx ok, no tx of any kind anywhere. HV is there but no rf out, no plate current...zip.
Sadly this rig was previously owned by a reformed cb'er, not to knock them too much but that was the way of thinking with this fella. The plate choke is pretty smoked and looks like some nearby resistors got pretty warm as well. This is the rig I've been looking for quite some time. I've a 520se perfectly operational on the desk and two 820s's on the floor (partially operational--needs work) I suspect I may use one of the 820's for parts if necessary. Any starting advice from you experts would be greatly appreciated!

Only resistors in PA cage are the two RF sens voltage dividers and they should be fine.

Need to look at the small VHF choke at the base of the RF plate choke and the RF bypass cap. Bypass cap body may be cracked,split,or hole blown in it. I would change it and the Plate block/coupling cap.

Need to measure the screen grid voltage at the 6146 tube socket pin to make sure it is approx 260vdc and not 300vdc. If 300 or more radio has been modified. Need to restore the SG from the 300 supply to the 210 supply at the HV rectifier board.

Also measure the cathode of the tube sockets to chassis ground and make sure very close to 5 ohms. If not change all four 20 ohm cathode resistors.

Measure the two 470 ohm pi-filter resistor (one on IF board and other on HV rect board) and replace if grossly high or low. Some folks jumper them out or parallel another resistor across them. Clueless!

Look at the two HV filter caps and see if the rupture vents are swollen and/or cracked. If so, replace both.

Pull the fuse and make sure it is a 6A fast blow.

Hopefully the power transformer has not been hurt. Can smell it and can see brownish liquid deposits dripping out of the core.

Just a few things for starters.

Hi guys,

I have given up with repairing my TS-820S. It does not show right freq. on digital readout, from time to time VFO goes wild, it does help (sometimes) if I turn band switch left/right to calm down VFO.

So I am willing to sell it for spare parts. Output tubes are great because I have never used this transceiver much, besides I have another set of spare output tubes. I have built in SSB and CW filters.

Anybody in the EU interested? If yes I will list it on ebay.

Operationally and electrically, nothing that I know of. I think the dash-one was the non-European Union version. Maybe some sort of export / import thing, but both filters have the same frequency and band pass, as well as connections and physical dimensions.

Only difference I can find in the documentation pages for the 88C, and the information available from the Kenwood dot co dot uk "discontinued equipment" site is that the dash-one has the words:

(Non-EU)

on the manufacturer's specifications page.

Anybody else got better data? Now I'm curious if there is something different.

CCR level should not be bandswitch dependent. CCR is derived from Carrier Oscillator CA-1. If the display is stable on 10 meters then CCR level is not likely the problem on 80 meters.

Only way to adjust CCR level on the R820 is to adjust the CA-1 carrier level. Could do that as an experiment, but not correct way to set CCR level. On the R820 KW replaced the TS820S TC-1 20pf trimmer cap used to set CCR level with a fixed 33pf C60 cap. Would have to change C60 value or replace it with a miniature trimmer cap.

You can see C60 and TP-1 and TP-2 on the IF-A unit board schematic.

A common problem with the display flicker is the rear wiper contact on the VFO main tuning capacitor.

I have fixed numerous 820’s with that issue using a little spray of tuner cleaner and a very thin contact file which fits between the end of the cap and the spring contact.

Worked every time.

Ok, Jeff. If you use -1 in TS-830s, TX and RX freq. is the same? One ham from EA wrote, he had a difference 1khz in his 830s. I do not why. Transmit is another story. IF freq in 820s and 830s is the same. If understand correctly, I need a little bit tune SHIFT.

Operationally and electrically, nothing that I know of. I think the dash-one was the non-European Union version. Maybe some sort of export / import thing, but both filters have the same frequency and band pass, as well as connections and physical dimensions.

Only difference I can find in the documentation pages for the 88C, and the information available from the Kenwood dot co dot uk "discontinued equipment" site is that the dash-one has the words:

(Non-EU)

on the manufacturer's specifications page.

Anybody else got better data? Now I'm curious if there is something different.

Victor,

I use DeoXit D5 for slide and rotary wafer switches. I apply small amount of D5 cleaner to a tooth then "gently", emphasis is on "Gently" scrub the wafer switch contacts then rotate the wafer switch 4 to 5 times throughout its range. If the wafer switch can't be accessed with a tooth brush, apply a small amount of D5 to the switch contacts then rotate the switch throughout it's range 4 to 5 times. Follow with generous amounts of canned air, compressed air can also be used, to blow out the switches and remove any residual cleaner left on the wafer and/or surrounding boards/components etc. This step prevents the wafer from "absorbing" the cleaner. I have used D5 and this method of cleaner slide and wafer switches for years and never experienced damage to any wafer or slide switch.

For pots, I use DeoXit F5 Fader cleaner/lubricant. I apply a small amount directly into the pot's opening then rotate the power throughout it range 4 to 5 times. I follow with generous amounts of canned air, compressed air can be used, to blow out the pot and remove residual cleaner/lubricant. Again, I have used this method for years and never experienced damage to a pot.

Victor:

Three ways to clean TS-820S and most of the KW Hybrid rigs rotary and slide switches:
1. Spray application with emphasis on the wiper and distribute the cleaner by rotating the wiper back and forth across all contacts in the 360 degree rotation. Very wasteful method.
2. Use a small soft bristle artist brush to apply contact cleaner directly to the wiper and all accessible contacts then rotate the switch knob back and forth to distribute the cleaner to all contacts. Even with an artist brush cannot directly access all of the contacts in the bottom of the arc. At best can directly touch 270 degrees or so. Have to rely on wiper to distribute.
3. Use the bendable plastic Microbrush applicators sold by Micro Mark Tools. These have a soft applicator ball on the bendable tip. Joe made us all aware of these tools. I have bought all three sizes and these do work better than an artist brush for applying cleaner to the bottom contacts in the travel arc. I use more of the Green colored Regular size.

The Screen Grid switch has 3 slots in the slide black phenolic body and easy to insert the small tip of artist brush or Micro Mark applicator into each slot and then let the cleaner wick down inside each slot via gravity and then cycle the switch several times.

As for relay contacts can use D5 on wetted paper and pull thru the contacts, but I prefer to clean electrically by application of current limited 5vdc to 12vdc (no more than 5 amps) across each NO and NC contact and key the relay closing coil multiple times. This method is less likely to remove the contact plating or to bend a movable leaf and change contact wipe.

Terry,

More great info from the man-in-the-know! Thank you.

My TS820s is about to have a speech processor alignment soon, and you were kind enough to give me detailed info on that, thanks again.

It looks like the push-pull processor on/off switch is also of problem as it gives the feeling the contacts are dirty.

Is this one of the switches that one must carefully drill 1 or 2 holes in to access for a spray cleaner?

Your comments would be greatly appreciated.

Bruce:

No need to drill any holes in the Processor push button switch metal housing.

Must come at the switch from the top left side.Working across the Mode switch decks. May have to gently move or raise up on lead wires and will see a hole in the metal switch body.

Can get the Deoxit D5 nozzle at this point or apply with artist brush. I heat shrink two D5 nozzles together to get into some places which allows keeping the can oriented vertically outside the radio.

I typically try to apply with artist brush first as often just spraying at as opposed to spraying in and easy to over spray. D5 carrier is very high concentration of naptha which is great solvent (just below gasoline on the fractioning column) and it does evaporate eventually, but silly to over spray. With artist brush can get some cleaner into the pot or switch and then if need to on these push button switches can force the cleaner into the contact area by small shot of canned air.

Wayne :

I think you mean the Cathode and SG resistors on the Final board and the 470 ohm pi-filter resistors on the HV rectifier board.

I would measure the resistors and if show no signs of deterioration and measure within tolerance leave them alone.

Easy to change to Final board resistors, but not as easy to change the 470 ohm. Have to roll the board over and be careful not to break off any wire wrap terminations. Quite a few folks cut the resistors off and then tack solder new 470 ohm on the top side stub leads, but I dont like to do that kind of repair on a customers radio.

Maybe, it will be interesting somebody
"
-- Actually, it is the YK-88C-1 filter with the different IF frequency. This is the newer plug-in filter mounted on a board for the Kenwood 940S or 850S. The filter for the 820S (YG-88C) is the same IF as the solder-in filter for the 830S (YK-88C). Both are 8830.7. The newer plug-in filters are 8830.0... The problem is just size, as the newer YK-88C is much smaller than the YG-88C and will not fit in the filter position in the 820. If you use RG-174 coax and wire in the filter you have, it should work fine."

56199. Hybrid Net Update (December 12, 2016)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-12-12 21:05:59 UTC
From: Mark Gilger
Topic: 56199 Message: 56199

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by me, WB0IQK. There
were 26 stations checking in under fair band conditions.

We had the following number of radios checking in.

1 running TS-520(x)
3 running TS-530(x)
1 running TS-820(x)
6 running TS-830S
0 running TS-510
0 running TS-511
0 running TS-515
0 running 599 twins
0 running TS-900

I was running my TS-830S + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
14 stations checking in FAIR band conditions.

We had the following number of radios checking in.

1 running TS-520(x)
0 running TS-530(x)
0 running TS-820(x)
7 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830S + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 ☐ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins
Nov. 2015 ☐ Oct 2016 Saturdays total 807 check-ins, Sunday total 628 check-ins

November 2016, Saturday net total = 80, Sunday total = 68
December 2016, Saturday net total = 24 , Sunday total = 32 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Hi Terry,

I finally got around to working on this. I have 2.9 volts at AF Board Connector 10, pin 3 and 2.9 volts at IF Board Connector 5 , pin 3. I thought next I would try injecting 3 volts into the ALC buss but not sure how or where this connection is.

Thanks, Scott, N6CIC

Scott: I dont remember what your issue is. Much water over the dam.

Apparently I had asked you to make sure that the ALC buss was hot leaving the AF board where it originates and is hot at the IF board. Measuring at Conn 5 Pin 3 doesnt tell you if the molex connector pin solder is any good or if you have a cracked trace (both common problems). Now need to make sure have 2.9vdc at Q30 gate or Q29 gate 2.

Assuming that you have RF-1 set for 3.6vdc and you are measuring 2.9vdc on ALC buss at AF board and 2.9vdc at IF board it appears you are using a 10 or 11 meg input Z meter and 2.9vdc is good level. The meter will pull it down approx 0.50vdc or so.

It is common practice to apply 3.0vdc from bench supply or batteries to the AGC buss when the S meter is pegged and have no Rx. If receiver comes alive then you know something is pulling the buss down and commonly it is failed meter FET.

Both the AGC and ALC busses are high Z power supplies fed from RF-1 thru a 2.2 meg series resistor and cannot support any load current . All they ever see is the associated RC time constant caps to ground and the gates of the gain controlled dual gate mosfets which presents no load to the buss.

Topic: 56036 Message: 56202

Hi Terry,

This is a no-transmit problem with my TS-830S, receive is fine. When in Tune mode with the meter set to ALC, flipping to send causes the meter needle to go to the top of the ALC line and just sit there. Adjustment of the Drive control has not effect on the meter.

I will check the voltages at Q30 Gate and Q29 Gate 2 and also lift the IF Board and look at the traces.

Thanks,
Scott, N6CIC

56203. Re: TS-830S No Transmit All Bands

Scott:

No need to lift IF board just yet. OK now I remember.

Any time in Rx mode the S-meter pegs full scale with the RF gain pot full CW most common problem is that there is no or very low AGC buss voltage. Less common would be a problem with the meter circuit.

Same thing when in Tune or CW mode and flip to Send and the ALC indication pegs. Again the most common reason is that the ALC buss voltage is very low or zero. Since you found 2.9vdc on the buss as it left the AF board and found 2.9vdc as it arrived at IF board you know the buss should not be at Zero. However, you dont know if the 2.9vdc is making it to the two active devices where they like to use it. Always OK to measure power supplies. However, not very useful if the path to the various loads is open. Weak link in all TS830s are the molex connector pin soldering and hair line cracks under the solder mask at the pin pad to trace transition. IF board is the worse as previous owners very frequently unplug and plug all the molex connectors primarily for cleaning and install and remove of optional filters.

This is why I said next step is to make sure the Meter FET Q30 is seeing the 2.9vdc voltage at its Gate and make sure that the TIF amp Q29 is seeing it at Gate 2.

If 2.9vdc is absent, then time to pull the IF board and inspect Conn 5 molex pin soldering (inspect all connectors). Also, if absent at Gate 2 of Q29 you could apply 3vdc from flashlite battery at Gate 2. Connect negative lead to chassis and touch positive lead to Gate 2. ALC indication should come off the peg. Do this in Tune with SG off and Flip to Send.

Terry K9TW

Hi Terry,

I was able to measure 2.9 volts at Gate 2 of Q29. I did this with the SG switch off, in Tune mode, meter on ALC, and flipping the Send switch. However I could not do the measurement on Q30. The area around Q30 is too congested for me to get my probe in to the Gate. Do you have a suggestion?

Interesting that in the above transmit mode, the ALC meter pegs all the way to the right until I touch the probe to the Q29 gate or to pin 3 of connector 5-then the meter needle drops to the top of the ALC line. I assume this is due to the DMM causing the voltage to drop from 3.6 volts to 2.9 volts. Is that correct?

Do you think Q30 might be shorted or it is not getting the ALC buss voltage?

Scott

Scott:
Yes---- your meter is the problem. This is why I went to lengths to explain how the AGC/ALC buss works so you would know what it means when you see a pegged S-meter either in Rx or Tx modes. At best a DMM that is 10 to 11 meg on all ranges will pull the buss down approx 0.50 to 0.60vdc. Some DMMs the input Z is range dependent and on a 3vdc or 5vdc range can be as low as 1 to 2 meg and will literally shut receiver down when you touch meter probe to the buss. So you must know your meters and test equipment specs so you can anticipate instrument effects and not be fooled into thinking you have a circuit problem and needless waste of time troubleshooting a problem that isn't there. This is especially true if the circuit is a high Z circuit like AGC or ALC buss.

Yes--- KW did us no favors with component side density and very short lead length on most active devices. Makes troubleshooting very difficult and sometime impossible from component side of the boards.
OK---given that you do have 2.9vdc at Gate 2 of Q29 TIF amp you now know that the path from the Molex connector is not open circuited.

Meter FETs do just get tired and fail shorted and when they do will cause standing S-meter indication. Before pulling the board and replacing Q30 if you can safely apply stiff 3vdc to gate 2 of Q29 go ahead and do so. Do it in Tune mode with CAR Level Pot full CW and VFO at 7.150 or 14.175 and Drive control at 1200 and SG switch off. You can use the RF relative power meter or an external wattmeter. Flip to send and touch positive lead of 3vdc to Gate 2 and adjust the Drive control for max RF relative power or max on the wattmeter. You can go ahead and load if you want, but not necessary as just want to confirm reason for no RF output power is due to no RF drive due to Q29 TIF amp not being fully turned on.
If this temporary dc control voltage at Q29 works to restore RF drive then go ahead and pull the IF board and replace Q30. Do not replace with an NTE sub or common MPF-102 device. Very sensitive to what device is used. Best to find a NOS 2SK19-GR off ebay and if cant find one maybe Walter Dilley can harvest for you. A good sub would be a 2SK192A.

Also, while IF board is out examine all the molex connector pin soldering for any signs of movement and any circumferential cracking around the pin solder. Need good lite and magnification. If find any best to remove old solder and file or sand the pin to brite metal and resolder. Make sure pin is fully seated into connector body on its shoulder.

Very nice TS-820, with digital readout, cw filter. Digital readout boards have been re-soldered and display works. Power supply filter caps replaced. With user and service manuals.

Also rare Russian Novosibirisk paddle Model #ARE80, "CW Siberia), manufactured in the early 1990s. Blue paddles.
Has built-in iambic keyer (PK-4) with solid-state relay that can key grid-block keying such as TS-820.

Pickup preferred on the TS-820 in the Harrisonburg, VA area. May have original box.

$375 together
$275 for TS-820, $100 for paddle/keyer

Address is good on QRZ

Scott

I am not telling you that Q30 JFET is bad. Just that it points to it being shorted. Also,while not very common, you could have a bad ALC RC time constant cap.

On rare occasions Q31 meter driver transistor can be bad. Not often have a bad VR-6 zero set pot or bad VR-7 span pot. You might note where set at and try running back and forth to see if makes any difference in ALC indication.

It would be good if you could bench test the board after replacing Q30. That would limit number of times that you may have to unplug and plug molex
connectors.

One last thing with rig turned off measure the resistance of the ALC buss to chassis ground at AF board Conn 10 Pin 3. I would say should not be much less than 450k ohms. If much less than that unplug Conn 5 on IF board and see if it goes up significantly.

Scott:

I forgot to ask where the CAR Level Pot is at when you flip to Send and see the ALC indication pegged hard? (with no DMM connected to the ALC buss)

Using a 10meg or 11 meg meter here are ALC buss voltages you should see with RF-1 set to 3.6vdc:

With CAR pot full CW the ALC indication should be pegged hard beyond the meter full scale at approx 1.8vdc. (not the black ALC range)

With the CAR pot full CCW should see no ALC indication at approx 2.9vdc

OK---I was under the impression that when you flipped to Send in Tune or CW Mode that the ALC indication was immediately hard against the peg. That means off the meter scale as far as it can physically go and cannot bring it back off the peg with the CAR level pot.

If you run CAR Level Pot full CCW where does the indication go?

Topic: 56036 Message: 56216

Scott:

Would like to stop and regroup. The more I think about this if you do have standing 2.9vdc on Gate 2 of Q29 TIF amp then you should be sending a TIF signal to the RF board TX Mixer and producing RF drive regardless what the ALC meter indication is doing.

Need to understand the dc voltage that you read at Q29 Gate 2 and repeat the test. Go to my website and look under Photos and can see a picture of a mini-grabber test lead clipped to a floral arrangement pin available at hobby shops. This is a good way to access leads of components.

By the way you can get on all three leads of Q30 meter FET. Cant get directly on the Source lead as it is the center lead, but can get on the left side grey solder connection of VR6 which is the Source. Would be good to measure the Source voltage. Should be 5.9vdc in Rx and approx 4.7vdc when flip to Send.

To measure Gate 2 of Q29 TIF amp in Tx mode set up as follows:
1. Mode CW
2. Heaters On
3. SG Off
4. Drive control 1200
5. Band 14 and VFO at 175
6. Flip to Send

Looking straight down on Q29 from front of the radio Gate 2 lead of Q29 is on the top right. In Rx mode you should read approx 2.9vdc.

With CAR Level Pot full CCW and Flip to Send should read 2.9vdc
With CAR Level Pot at 1200 and Flip to Send should read approx 2.0vdc
With CAR Level Pot full CW should read approx 1.5vdc.

If the 2.9vdc level drops with the CAR level pot advanced then you have to be producing some level of TIF signal which is reaching the TX Mixer on the RF board and producing RF drive to the Driver tube and the Finals. This would mean the problem with a standing ALC indication that you cannot peak is limited to the metering circuit of Q30, VR6, VR7, and Q31.

If 2.9vdc doesnt drop with CAR Level pot advanced when you flip to Send repeat the test on 3.750 and/or 7.150mhz.

If 2.9vdc doesnt drop on any band with CAR pot advanced need to measure RF drive voltages beginning with the TIF signal on IF board at Conn 6. Need to run TX Level Diagrams.

Do you have a means of measuring low level rf signals ie O-scope, RF probe for your DMM? If cant measure TIF signal, do you have a good RF sig gen? Can inject a test TIF signal.

One last question:
Since you have owned this radio have you been able to load it? How familiar are you with

loading the radio?

Bruce,
  You can find what you need at an ACE Hardware store, or any largehome improvement store. The case screws are: M4 X 8mm stainless Phillips panhead screws, the ones for the speaker are: M3 stainless Phillips ovalhead. Ken Kemski k4eaa"dot"com has a package of what you need (24 screws) for about $4-$5 bux + shipping. I've purchased some before...and they are an excellent replacement. Also, I think hybridrestore"dot"com may also have some

Hi Terry,

With the SG switch Off, the mode to Tune, and the meter on ALC here is what I get:

With the Drive fully CCW, and flipping to send, the meter goes just to the top of the ALC line and when I touch the ALC buss (Connector 5, pin 3) with my DMM probe the meter goes to 90% pegged. My DMM reads 2.90 volts.

The exact same thing happens if the Drive control is fully CW.

Scott

Scott:

Any time you connect at 10 meg meter to the ALC or AGC buss it will drive the meter up scale.

As I previously stated with RF-1 set to 3.6vdc there will be 3.6vdc on the buss and when you touch your 10 meg DMM to the buss it will pull the voltage down from 3.6 to approx 3.0 and will drive the meter up scale. If ALC zero has been properly set (just coming off the stop) then it should drive the meter to approx the letter C in the ALC box.

Have you tried setting the ALC meter Zero by adjusting VR-6 (heaters off) ? Flip to Send and adjust indicator to just barely start to come off zero.

I have asked a several key questions and dont seem to get answers so not sure I am communicating effectively. I think I have given as much help as I have to offer.

Hi Terry,

I am sorry but I missed a previous post where you asked a series of key questions. This is where you asked me to repeat the test on measuring Q29, measure Q30, and you asked if I could measure Rf voltages and to run a TX level diagram set of Rf voltages.

You also asked if I am familiar with loading this radio.

I have a homemade Rf probe and I have run a set of TX level diagram Rf voltages before on a different KW hybrid radio. I don't have an O-scope or an Rf signal generator.

I am familiar with loading this radio as I have owned a TS-530S for a long time. Prior to that I owned a TS-520S.

As I have to attend a funeral over the weekend I will not get back to working on this radio until next week and it will take me some time to run all of the tests and to answer your questions properly.

I thank you very much for all of your help and I will endeavor to run the tests as carefully as I can and to respond as accurately as I can to your questions. I am sorry if I have caused you frustration and I thank you again for your help.

Scott:

When you return from the funeral and get time to get back on this problem could you give me a phone call. Would save a lot of key strokes for me if you could be sitting in front of the radio and discuss course of action.

Would like for you to try to load the radio by peaking the drive in Rx mode and then proceed with initial plate current dipping and then loading via RF relative power meter or external wattmeter.

We need to know if this is a loss of RF drive problem or an ALC indication problem.

My phone is 269-663-8943

You dont mention that you have the Heaters on? Need the heaters for RF drive output from the Driver tube and for cathode emission from the Final tubes.

SG is off as no need to engage the Final tubes multiple times and when they may be looking at a Tank circuit that is in off resonant state. Just need Finals for cathode emission and proper operating bias at the control grids.

I hope you mean the CAR Level pot and not the Drive control?

The Drive control should be at 1200 position for doing this test at 3.750, 7.150, and 14.175mhz. The reason for 1200 and the three bands is because on a reasonably well aligned 830 the peak in RF drive voltage at the control grids of the Final tubes should occur close to 1200. You should be swinging the Drive control left and right of 1200 to see if makes any difference in ALC indication and voltage that you read on the DMM. The reason for the 3 bands and specific frequencies is because of potential for bad bandswitch contacts not switching in the necessary tuned circuits and the three specific frequencies aligns with peak close to 1200 on Drive control. Three bands because not likely to have all with bad BS contacts.

If you mean with the CAR Level pot at full CCW the meter is indicating near the top of the black printed ALC scale then I would attempt to bring it down to zero with the zero set trim pot VR-6.

When you report that the ALC indication goes higher when you touch DMM probe to the buss and the meter reads 2.90vdc tells me that prior to touching the buss that there is 3.6vdc on the buss.

That means there should be a TIF signal produced when you have the CAR Level pot advanced to 1200 or greater. The reason for 1200 or greater is to ensure that the Balanced Mod diodes are turned on hard. Need around 0.300vdc to overcome the diodes barrier junctions.

It is possible to have no ALC indication and be able to load the radio. Perfect example of this is turning the mic gain down in SSB mode until there are no ALC indications on voice peaks. Can work the world this way proving that there is RF output yet no ALC indication. You need approx 43 rms RF volts at the control grids of the Final tubes to overcome the dc offset that the operating bias presents. That bias for 60ma resting plate current is approx -60vdc. 43 x 1.414 = 60.8 volts on positive going peak of the RF drive envelope. Just enough to cause the control grids to become positive with respect to the cathode and cause ua grid current to flow in the FG line. That ua grid current biases on the ALC amp transistor and produces a negative voltage at its collector which bucks the 3.6vdc ALC buss voltage and Q30 meter FET gate sees this lower buss voltage and drives the meter indication up scale.

Any RF drive voltage lower than approx 43rms volts will produce RF output from the 6146 PA, but there will be no ALC indication. This is why I asked you to try loading the radio using a work around ie peaking the drive in Rx mode either using the receiver back ground noise or the marker. Some folks load this way all the time or just on one band and sadly think it

is normal. Can also use the RF relative power meter position or an external wattmeter to accomplish peaking the Drive in Tune mode.

So when I ask you to do something it really isnt a request. It is direction to be followed and it isnt just willy nilly guessing. Each item is asked for a reason.

I cannot expend the key strokes to explain in this level of detail each time why I ask for a step or test to be done.

Only way I can continue to help is if we take this off the forum and you call me. Could have told you the above in fraction of the time and can ask clarifying questions and gauge more effectively if you understand the directions.

I post the following in hopes of helping others avoid the same mistake. There I was, working on another TS-830S, flipping it over to make another adjustment on my list when I heard the dreaded “snap” and smelled a strange smell. I say strange because it wasn’t like the smell of a burned resistor or wiring. I have surely smelled those before. This had a distinct metallic smell. This bad sound and odor came from the rear of the RF board where the hanging loose speaker lead had fallen. At this point I still had a good receiver, but no transmit at all. No drive to be seen. I still had proper idling current on the final amplifier.

I measured the voltages around the 12BY7A tube and found that all was well except there was no 4.6VDC on pin 1 as there should have been. I removed the RF board and did a cursory inspection of the components near the rear of the board and around the driver tube. Nothing jumped out at me. I installed another board and it worked fine, so it had to be on this RF board.

I inspected the cathode components associated with the driver and all was well. The tube seemed to have all that was required for there to be cathode voltage, but it had none. My non-technical mind said this has to work. The only voltage that I had not checked was the filament. So, I measured the resistance from connector 9, pin 1 to the filament connection at the tube socket and had infinity - open. Another closer inspection of the board revealed a burned and open trace on the board between pin1 and L39. Looks like the hanging speaker lead had come into contact with the top of L39 and taken out the trace. Bridging the open trace fixed the problem. I put the board back into the radio and did the happy dance.

Lesson learned is to somehow cover the speaker lead to prevent this from happening again. I have always been a bit afraid of that lead flopping around with a good ground wire attached to one of the pins. For right now, a bit of electrical tape over the pins will have to do.

Dick

I took the mating connectors off couple of KW hybrid speakers from parts rigs and placed heat shrink sleeve round them.

I simply plug the speaker plug on the end of the yellow lead wire into this insulated "cap" and then no concern about either the ground pin or the "hot" output pin contacting chassis ground or contacting any potential.

In addition to not want the ground pin to contact energized points I dont like to place an accidental ground on the Audio Output Amp hot pin.

I also dont like to run the Audio Output with no load on it so I always work with remote speaker connected.

Can send you a picture of the insulated cap if needed.

Thanks for the picture, Terry. That was the first thing that came to mind, but couldn't find a speaker that I wanted to steal the connector from. All of the extra speakers that I have are in good shape including the connector. I will keep looking. Yes, I always use an external speaker. That is the first or second thing I do when I put a radio on the bench. The other is to connect the dummy load. Those leads are readily available on my bench.

I never cease to be amazed at what an old fellow can learn from day to day about these radios.

Hope all is well there for you and your family.

Dick:

I had a couple of speakers that were very rattly/tinny so willing to sacrifice them.

You can also just slip a piece of small diameter heat shrink tubing over each of the two pins. Can find an inside diameter that is pretty snug and no need to heat shrink them on. Of course could do that and cut off after all service is completed. That is how it did it on the 530/830 series until could harvest the female jack.

Date: 2016-12-18 18:42:39 UTC
From: Mark Gilger
Topic: 56240 Message: 56240

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by me, WB0IQK. There
were 18 stations checking in under POOR band conditions.

We had the following number of radios checking in.
4 running TS-520(x)
3 running TS-530(x)
0 running TS-820(x)
4 running TS-830S
0 running TS-510
0 running TS-511
0 running TS-515
0 running 599 twins
0 running TS-900

I was running my TS-830S + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
8 stations checking in FAIR band conditions.

We had the following number of radios checking in.

2 running TS-520(x)
0 running TS-530(x)
0 running TS-820(x)
73running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830S + Drake L-4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 ☐ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins
Nov. 2015 ☐ Oct 2016 Saturdays total 807 check-ins, Sunday total 628 check-ins

November 2016, Saturday net total = 80, Sunday total = 68
December 2016, Saturday net total = 42 , Sunday total = 40 (Month to date)

Hi all,

I'm refurb'ing a TS-830......So far I've done a total electrolytic recap, rebuilt the bandswitch boards (love that Wright's Silver Cream).

I bought this rig specifically to rebuild. When I first opened the box, this rig REEEEKKED of cigarette smoke (separate issue later). Now I want to clean and lube the pots and switches. I'm thinking about an isopropyl alcohol contact cleaner (99% pure. and good flushing action, https://www.grainger.com/product/1HBK5?gclid=CJWWiInngNECFZCPswodLVcCVg&cm_mmc=PPC:GOOGLEPLAA-_-Cleaning-_-Cleaning%20Chemicals-_-1HBK5&AL!2966!3!56542746957!!!g!102362316837!&s_kwcid=AL!2966!3!56542746957!!!g!102362316837!&ef_id=VOM5fQAABNUYogiB:20161219174222:s https://www.grainger.com/product/1HBK5?gclid=CJWWiInngNECFZCPswodLVcCVg&cm_mmc=PPC:GOOGLEPLAA-_-Cleaning-_-Cleaning%20Chemicals-_-1HBK5&AL!2966!3!56542746957!!!g!102362316837!&s_kwcid=AL!2966!3!56542746957!!!g!102362316837!&ef_id=VOM5fQAABNUYogiB:20161219174222:s) that I can just spray the bejeebers out of the pots and switches, then go back and lube them (De-ox-it F5 and D5?).

So is this a good plan of attack, or should I go a different route? Different products?

I also need to clean and lube the ball bearings, I think there are 5 or 6 of them.
AND I need to C&L the VFO gears.

Suggestions?

Thanks,
Bob--KD8WU

I'm repairing/restoring classic HiFi-equipment from yesteryear (mostly japanese manufacturers from the 70s). A lot of these have been in smoker households. You'll notice this immediately, but it gets worse when the thing heats up.

After searching a long time for a remedy, I found an article from a Tektronix publication:

http://www.radiomuseum.org/forum/tektronix_washing_your_instrument.html

These guys put the whole scope (tube or transistor) in a washing box and cleaned the whole thing (opened, of course) with a mild detergent solution and lots of water. After the washing the scope was blown out with pressured air and dried in a climate chamber at 50deg C. Any repairs or adjustments were done after this procedure.

I tried this with a Yamaha Hifi-Receiver (CR-2020) from 1978/79. One of its owners was a heavy smoker, and I had problems to touch it without gloves. The silver front plate was dark yellow, you couldn't see the scale properly behind the blind glass and it smelled like an uncleaned ashtray. After removing the wooden upper enclosure and all knobs, I put the whole thing into the shower, watered it and used bathroom cleaner in a spray bottle to add a liberal coat of detergent to the in- and outside. After a few minutes this was washed away with the showerhead and a soft brush. After a few applications the brown crud started to go away. Finally. it looked clean. It was wintertime, so I put the Yamaha on a warm radiator and let it dry for a few days.The knobs were cleaned in the ultrasonic cleaner.

The dried receiver was tested (as usual with "unchecked" ebay-buys, the final transistors were gone) and repaired. Following the service manual, the radio part was adjusted and the power amp idle current set to the correct value. The finished receiver sits in my living room, puts out 2*130W into the speakers and works perfectly and without smell.

About your question: when overhauling my TS-830S, I removed the (rather dirty) RF board, desoldered the wavers from the board with a vakuum desoldering gun and cleaned them by quickly washing them in the ultrasonic with a mild cleaning solution. Don't let phenolic boards sit too long under water (hours or longer). 1min in the ultrasonic and washing them with demineralized water before gently drying them with a heat gun gave no problems. The pots and smaller switches were cleaned with Oszillin T6 (a spray like Deoxid).

Hi Terry,

I know you asked me to call on this topic, but I just completed a series of tests that you suggested and since I am on the west coast, it is too late to call you, and I thought I could summarize my results here.

I bought this radio on eBay and have not been able to load it since it arrived. However I also own a TS-530SP and I am familiar with the loading procedure.

First I tried to load the radio with the drive control peaked in receive and the radio hooked to an external watt meter. Heaters On. Resting current was 60 ma. Carrier pot was at 11:00. I could not get an indication of loading the radio in Tune or CW mode. There is no indication of Rf drive, either at 7.150 or 14.175. No dipping with the meter on Ip or loading with the meter on Rf. No sign of power output on the external wattmeter.

I next measured Gate 2 of Q29 TIF amp as follows:
Mode CW
Heaters On
SG Off
Drive control 1200
Band 14.175
Flip to Send

With carrier level pot full CCW and flip to Send---2.9 vdc
With carrier level pot at 1200 and flip to Send--2.9 vdc
With carier level pot full CW and flip to Send--2.9 vdc

I repeated the test at 7.150 and got exactly the same result.

From your note, I believe this means I am not getting a TIF signal and I am not getting Rf drive to the driver tube.

My next test will be to measure Rf drive voltages beginning with Conn. 6 on the IF board. I will run a TX level diagram series of measurements. I will have to use my home made Rf probe on my DMM. Since it is close to Christmas, this will be a little hit and miss as I find time. Once that is done I will call you, likely after Christmas.

Thanks for all of your help and best to you and your family during the holidays.

Scott, N6CIC

OK--With 2.9vdc ALC buss voltage on Gate 2 of Q29 TIF amp should be producing a TIF signal at output of the IF board. With CAR level pot at 1200 to full CW position should be biasing on the ring diodes producing carrier at output of the BM.

TIF at Conn 6 will be low level around 40mv rms or less. If your RF probe has a germanium signal diode you may not be able to read 40mv on your DMM due to the diode requiring approx 300mv to turn on hard. Make sure you swing the Drive control around either side of 1200 position and may be able to see10mv to 15mv dc as you detune the LC circuits.

Best to measure TIF with O-scope. It is a harmonic rich sine wave due to VCO signal leak back from RF Board. Best if have scope with digital low pass filter capability, but older scope can be employed.

If you cant see any TIF at Conn 6 move to TP-4 on the RF board which is the output of the TX Mixer. Should see approx 2.0 to 3.0 rms RF volts. Dont be afraid to set CAR Level Pot full CW and swing the Driver control each side of 1200. Your RF probe/DMM should have no problem measuring RF output of the TX Mixer. This will not be the 8.830 carrier. This is the actual transmit frequency.

Could be several reasons you dont have TIF from IF board including:
1. No carrier at input of the BM--Measure carrier at TP-2 with RF probe/DMM. About 1.0rms RF volts at 455khz.
2. No CV diode bias at BM--Measure CV at Conn 8 (0-9vdc)
3. No carrier at output of BM---Measure RF carrier at cathode of D34 (easy access). About 100mv. (may be as low as 30 to 40mv with your DMM)
4. No carrier at output of Q29---Measure RF carrier at Drain of Q29

More later if measurement confirms BM has what it needs to work.

I had a 530 that I restored. It had a very thick coat of nicotine and was very nasty. I completely disassembled and washed the board. The nicotine film melted off and left a very new looking fresh appearance. I let everything dry out about a month before applying power. I was suggested on this forum to get deoxit pot lube. I have a bottle and use it sparingly on all pots. Believe me, it will bring them back to life.

Scott:

I did not force rank the troubleshooting steps.

If rig was on my bench I would look for TIF at Drain of Q29. If it is there then you have a problem at Molex Conn 6 Pin 3. Either cracked solder at pin pad or a cracked trace at the pin pad to trace transition area. Two common problems with IF board Molex connectors. IF board molex connectors more susceptable as they endure more unplug and re-plug cycles than other boards. Never intended to see these cycles.

If no TIF signal at Drain of Q29 then go ahead and confirm that the BM has Carrier and CV. If they are present then measure output of BM at D34 cathode. It is possible to have bad ring diodes, but not common. If no Carrier or CV present at BM then again problem most likely due to bad associated molex connectors.

I am sorry too big a hurry this am. One last thing.

Do not assume you have CV at BM just because you have 0 to 9vdc at Conn 8. Must also measure CV at Cathode of D30 at BM.

Should see 0 to 250mv there when running CAR Level pot from full CCW to full CW.

For what it's worth, on older tube only rigs (1940, 50's, 60's) I regularly spray them with Simple Green (a degreaser), let it sit for a minute, and then hose it off gently in the driveway, making sure to dry them thoroughly with either compressed air or a hair dryer (and, for good measure, usually waiting a few days to make sure everything gets dried out well) -- which does wonders for removing gunk, grime, cigarette smoke, etc. I have not done that with the hybrids, however -- but as long as you avoid any moisture sensitive components (ie. speakers or anything with paper) most circuit boards are remarkably tolerant to cleaning. I've literally removed 50 years of dirt from a transceiver sitting in a barn using this method and after the usual restoration had everything come back to life!

Similarly, with newer Kenwoods (I've done with with TS430's and TS440's) I have removed and cleaned the boards and grime covered parts with Windex window cleaner (*NOT* the vinegar version) with great success, which avoids any possibility of water hanging around to corrode metal. Windex evaporates fairly quickly, although an air compressor or hair dryer also works to accelerate the process and make sure it is removed from nooks and crannies. I have not wholesale Simple Greened any newer ones because the boards are packed in there and water can linger -- but I wouldn't hesitate to pull boards out of the box and do the same.

I then use Triflow or Deoxit on any pots, wafer switches, etc. (sparingly and often using a toothbrush on the wafers very gently) to get all those contacts working again, protected, and lubricated.

Anyway, my 2 cents.

Topic: 56113 Message: 56254

OK, the HI-LO switch was added by one of the previous owners. I adds a 22K resistor in series with the 210V screen grid line at the HV Unit board (210V connection point) in the "LO" position. The 22K resistor is shorted in the "HI" position. Apparently, the mod was to have a "low power" option when in CW, USB, or LSB modes.

I have a Heathkit SB-610 Station Monitor and need to connect to the second IF output of a TS-520 to monitor in-coming signals. Has anyone in the group done this? If so, where is the connection made? I am assuming a low value coupling cap to the final IF amp collector would be appropriate? Any help is greatly appreciated.

The SB-610 really shows its usefulness in monitoring your transmit signal. While the vertical input can be connected to a IF output of a receiver, it really doesn't show or tell you much about a receiver signal. It will also only show you the signal that you're listening too. The SB-610 is not a band scope/panadapter/spectrum analyzer. On the receive side, it just pretty eye candy. Also, the IF input of the SB-610 has to match the IF output of the TS-520. Most likely, a buffer amplifier might be required to boost the signal enough to drive the vertical input of the SB-610. Cable length should be reasonably short (2 ft or less) between the two pieces of equipment.

Thanks, Pete! I know the receive IF monitoring does not provide very much useful information, I just thought it would keep the screen trace moving to prevent phosphor burning when not transmitting. Probably too much trouble to mess with an op-amp installation, I'll just keep the intensity level low. The SB-610 does give a real vintage look to the station and I really like working on stuff that I worked on in my youth, when the stuff was new. You must forgive an old man and his ramblings about the past.

Bill:

If you ever need to do something akin to that again, instead of dishwasher soap use about two tablespoons of "DAWN" brand hand dish-washing soap. Put it in right at the beginning of the shortest wash cycle, and just put it in the sump or drizzle it right on the equipment you're cleaning. Don't use the little door or cup that opens during the wash cycle.

(I'm not generally brand-conscious, but "DAWN" brand just works a lot better than the generic stuff.)

Not in small quantities. I've done it several times, latest being a Heathkit oscilloscope, an O-10 IIRC, or maybe it's an O-11. (Anyone interested in buying it from me (cheap, I've too much clutter - but you have to pay packing and shipping - and I'll dig it out and check to be sure which one) More than a spoonful or two of Dawn and yes, you would be right, you could have a serious foaming problem. But it works a treat on old cases and chassis parts. Gets the stink and grime off quickly.

56270. Final decision: TS820S to be dis'assembled after multiple failures , try to recycle parts

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-12-21 22:05:25 UTC
From: Prof. Arnaldo Coro Antich
Topic: 56270 Message: 56270

Dear amigos: It is all over now...

Every time something that was going wrong was fixed, new problems showed up.

So I have decided to proceed to dis-assemble the TS820S in order to recycle as many parts as possible for future use...

The external VFO will be used , with a very simple modification to feed an ailing Ten Tech 540 that has a broken VFO for which there are no possible repair options.

The external loudspeaker will also go the the Ten Tech 540

But... What to do with all the parts that can be used to fix other radios , or to provide the components for completing an ongoing SSB single band transceiver...

The power transformer is OK, so it will go to a new power supply for the home brew single band much simpler hybrid rig.

Advice is requested on ideas of how to make the best possible use of the other parts, like quartz crystals, the SSB filter, the possibility to remove the main VFO and also the final amplifier module...

Many electrolytic capacitors tested show the ill effects of the more than 30 years or perhaps 40 years since the radio was built.

Sad end to a huge effort that ended in failure...

FWIW, Dawn dish washing soap is what they clean crude oil soaked wild animals with (birds, seals, otters, etc.) and it's about the most benign detergent available for grease and tar clean up out there. Sparingly and minimally used it works better than just about anything. Dishwasher or by a gentle application of dilute Dawn solution sprayed on, soaked for a bit, then rinsed and thoroughly dried will not generally hurt any electronic device. Paper, and some insulated wires excepted. Certainly not resistors, caps, ferrite coils, ICs, and disrete semiconductors, etc.

The motherboards for personal computers and most anything else for modern electrinics are washed in essentially big dishwashers. The typical flux used commercially is a mildly acidic flux which is water soluable. These fluxes have surficants in them and don't generly need an added detergent, but a small amount of a detergent like Dawn cuts down on the necessary wash time. These fluxes are liquid in use, and are corrosive if not cleaned off in a few days. But once cleaned, there are no corrosion issues.

I used a lot of Kester type 331 flux in our prototype lab and cleaned it off with warm clear tap water, a tiny bit of Dawn, and a deionized water rinse. The proto boards sparkled and clearly showed superior solder joints and workmanship. I was hesitant at first to use an acid flux (evan water soluble) in electronics but these mildly aggressive Kester style fluxes area what the big boys use and completely clean from their boards in a manufacturing environment.

I think you mean L8 on the TS820S Coil Pack board.

There is no L41 on the RF board of a TS820S.

L8 can be hurt by accidental Transmit RF, but it is a bit more hardy than the TS830s L41 Ant Step-up transformer. Probably see failure on ratio of about 10 to 1.

Perhaps you should ask for the Coil Pack board(horz board) and the RF board (Vert Board). If you get the RF board make sure to measure the Driver tube screen grid divider resistors R13 and R14 before installing it. Very common for R13 82K to be very high or even open. This can shorten life as it supplies a higher level of screen grid voltage to the Driver tube.

Deserthound :: TS-520/820 Series PA Modifications
http://www.deserthound.com/amateur-radio/ts520-820.html Introduction

View on www.deserthound.com http://www.deserthound.com/amateur-radio/ts520-820.html
Preview by Yahoo

I am wondering how this conflicts with many of the recommendations to "NOT" increase the PA cathode resistor wattage and to "NOT" use wire-wound resistors. He seems to have some good points, especially in using wire-wound resistors for the screen grid 100 ohm values (added parasitic suppression benefit).

Thanks,
John

John:

The deserthound mods are interesting, and they appear to be well thought out and explained. I also have often wondered why others have indicated that the cathode parallel resistor group, and the screen grid resistors, should be non-inductive, and should not (for the cathode R's) be increased in wattage rating. In both cases, I don't see any reason why inductive (e.g., wirewound) resistors cannot be used, since the cathodes and screens are bypassed for RF at the tube terminals. Also, I don't see why higher wattage ratings are considered to be a no-no by some. If the cathode resistors are considered to offer some measure of protection (similar to a fuse?) then what exactly are they protecting in this manner? Since it's already recognized (I think) that a series string of three 1n400x diodes is advisable (as a mod) from 6146x tube cathodes to ground to protect against an overvoltage to the Ip metering circuit in the event of a 6146x plate-to-cathode fault, I believe a higher wattage set of cathode resistors is unlikely to do any harm; I think it's more important to protect the meter than to try to protect the 6146x tube(s) if they are already flashing over internally. But I certainly welcome any comments on this from other group members.

The other mods described by deserthound related to reduction of IMD are interesting. But I have to admit that I need to learn more so that I can try to understand them.

This subject and this article has been discussed on this forum at length and lets just say it caused some spirited debate.

Of course it would be better to have a regulated Screen Grid supply in grid driven tetrode class AB-1 linear amplifier. However, KW design engineers elected not to include as did most of the other SSB transceiver manufacturers of the middle 70s to early 80s.

Primary reason was cost/benefit. Screen grid protection also comes in to play, but many hours of operating experience with the as built hybrid design has proven that Final tubes are not lost due to exceeding S2001A or 6146B SG dissipation ratings due to having an unregulated SG supply.

Back then it was not easy task to build a regulated supply. There was the weight and space requirements of extra transformer, rectifier, filter caps, filter chokes, gas VR regulator tubes and of course the additional costs. Wasnt easy or cheap to install regulated SG supply back in the mid 70s to early 80s. So if you like you can say that KW took the "budget" approach to this aspect of the Hybrids design just as Yeasu and others did.

Today with Zener diodes or better yet Mosfet shunt regulators it can be done easily and not much space requirement and not much additional costs.

The primary reason to regulate SG supply is for improved linearity ie lower IMD ie less splatter on the bands. Why does unregulated SG supply effect linearity? Because the SG is the real anode and has the primary influence on the plate current. A change in SG voltage can cause the zero signal plate current or Q point to shift along the load line. With full anode swing under RF drive can result in operating in less linear portion of the transfer curve.

The TS820S and TS830S have much improved IMD performance over the earlier Hybrids because they employ ALC and RF negative feedback. Addition of a regulated SG supply isnt going to make significant improvement in IMD. It would no doubt help with the TS520 series rigs. However, it should be pointed out that the operating manuals for these radios dont even call out the 3rd order performance. It isnt until we get to the TS830 that we see a spec of greater than -36dB. You have to go to the TS820 Technical Supplement pg 11 to see that 3rd order products are -25dB without RF Neg Feedback and -35dB with RF Neg Feedback.

If you want to read about why well regulated SG supply is a must for a tetrode read the works of Ian White of the Tetrode boards and/or go to W8JI Tom Rauch website and read about why regulated Screen grid supplies.

The average KW hybrid owner does not own a calibrated Spectrum Analyzer so I am not sure how they would ever be able to perform before and after measurement of IMD products to verify that the addition of a regulated SG supply resulted in less IMD? Without measurement mods results are very often just "feel good" results.

As pointed out my first and only hybrid mod would be diode string across the cathode meter shunt resistors.

Thanks, Terry! Very informative and useful reply. I may experiment with the regulated SG supply mod for my TS-520 but I will probably stick with the original KW design. Apparently these rigs have been operating just fine since the 60's, as long as tuning and operating guidelines are followed (with the occasional replacement of components due to aging).

The single-most "plus" that I have for these radios is that one can troubleshoot and repair them using traditional test gear (that's all they had back then). Even obsolete components can be replaced with current devices (with some ingenuity).

Thanks to all for their replies!

John:
There is no doubt you could improve 3rd order IMD on your TS520 by adding regulated screen grid supply. I have looked at spectral content of quite a few and the TS820 and TS830 are better than the 520 series by at least 10dB due to improved ALC and RF negative feedback.

Lots of debate about FCC Part 97.307. Some will argue that there is no explicit phone band limits for IMD where others will site the -30dBc limit and still others will hang hat on 97.307B which says you cant splatter on adjacent frequencies.

Also, some controversy over what you will see in the ARRL handbooks. I have quite a few handbooks and for example in 1977 edition under Testing a Sideband Transmitter it states under the 2-tone testing discussion that ...."a good waveform means that the IMD products are at least 20dB below the desired tones". My comment here is that what the FCC says on the subject is what really matters.

About the best I have seen on the TS520 rig is approx -25dBc which means the 3rd order products are down 25dB from the fundamental. Not very good by todays standards.

Maybe you can ask on air if someone with SDR panadapter can take a look at your signal for you?

So what would I do if owned and operated a TS520 series radio? I would make sure to adjust the mic gain to keep the ALC inside the black printed scale and I would observe good operating practice and not park close to in progress QSOs and probably ask someone to tune across my signal or look at it with panadapter. Asking someone to tune across your signal assumes they know how and what to look for.

I wasnt trying to discourage you from modifying your TS520. For many mods and experimenting is the essence of the hobby. Maybe Jan will install shunt regulator in his Hybrid and has means to measure before and after IMD and can report back results.

Terry,
It's coming, I have been wanting to do this for some time, just to see how better it can be.
Currently working on a TS-510 and I'm not happy with the HV (210v & 150v) regulation. I'm designing & prototyping a solid state voltage regulators to replace the regulator PCB that is based on using a 6BM8 tube. I would advise other 510 owners on using a variac to power them up. My regulator wasn't working and I'm sure the tube life would be cut very short if powered with current line voltage (124vac)

Nice read Terry. I wish someone would make a board for the screen and driver caps. Doing the 8 lug terminal strip is a real PIA. The caps I got would not fit doubled up in the old cap holder.

56290. Kenwood Hybrid Net Update (December 24, 2016)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-12-25 03:57:59 UTC
From: Mark Gilger
Topic: 56290 Message: 56290

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started its existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday net was run by me, WB0IQK. There
were 20 stations checking in under POOR band conditions.

We had the following number of radios checking in.
1 running TS-520(x)
3 running TS-530(x)
3 running TS-820(x)
4 running TS-830S
0 running TS-510
0 running TS-511
0 running TS-515
0 running 599 twins
0 running TS-900

I was running my TS-830S + Drake L-4B amplifier.

There was no Sunday net due to it being
Christmas. I hope everyone has a very nice Christmas and a happy new year ..

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit

and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
Nov. 2014 ☐ Oct 2015 Saturdays total 962 check-ins, Sunday total 669 check-ins
Nov. 2015 ☐ Oct 2016 Saturdays total 807 check-ins, Sunday total 628 check-ins

November 2016, Saturday net total = 80, Sunday total = 68
December 2016, Saturday net total = 62 , Sunday total = 40 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Rory:

I dont replace with 4 axial or radial lead caps in the 520 series or 820 rigs.

I replace with Richey Golds dual can 20uf @500wvdc. Buy these from Just Radios in Ontario, Canada.

Slightly smaller diameter. Just slip a small band of 1" heat shrink at the clamp band area and heat shrink in place so that the original clamp will tighten and secure.

56293. Caig PTFE Dry Lube

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-12-28 14:53:38 UTC
From: bobcolenso@...
Topic: 56293 Message: 56293

Many people here really like Caig products like their D5 and F5 products.

I am refurb'ing my first TS-830s, so I'll probably be here often (that was my "de-smoking" thread). I was looking for a dry lubricant to use for the bearings and VFO gears. Googling "dry lubricant" I stumbled on this CRC Dry PTFE Lube
http://www.crcindustries.com/ei/product_detail.aspx?id=03044
http://www.crcindustries.com/ei/product_detail.aspx?id=03044 that I was thinking would be good to use on both the gears and bearings as a dry lube that does not attract dust or dirt.

So, is this a viable option, or is there something different/better that I should use.

Thanks,
Bob--KD8WU

56295. TS 530S Dip in wrong part of plate dial?

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-12-25 05:50:51 UTC
From: remingtonhill1@...
Topic: 56295 Message: 56295

Sorry if this is a double post, I don't see my first attempt.

My radio tunes up all bands normally, but 80 meters. When in tune mode in band "3.5" , and dipping the plate, it doesn't dip until the plate knob is positioned in the 7 Mhz area of the plate dial (upper part). It's only at this part of the plate dial is it putting out the appropriate power in tune mode (~15-20 watts). I didn't try tuning at full power because of this anomaly. I'm doing this into a dummy load.

Any Ideas?

Thanks,
Shane

73, KG5RJS

56296. Tuning up 75 meters, but plate dip occurs at 40 meter position on the plate dial.

Yahoo group: TS-520_820_530_830 (2015 — 2016)

Topic: 56296 Message: 56296

Just like the title says. All the other bands function normally, but but I don't see an "ip" dip until I move the plate dial just past the 7 Mhz. position. This is in "tune" mode into a dummy load.

The Radio shows proper tune output (around 15 watts) on the wattmeter inline with the dummy load.

Any ideas?

Thanks,
Shane

I have a TS-520 that has a band specific tuning problem. On 14/21/28 everything is OK. Bias, carrier, drive, loading, tuning dips, frequencies all OK for a 100W output. On 3.5/7, bias, carrier, drive, frequencies all OK. However, Ip goes up to 340ma and no dip achievable. Checked tank caps/bandswitch. All OK. It's as if I am under or over coupling. The HV is OK. The 6146's and 12BY7 check OK (voltage wise). Fault is probably staring me in the face. Any advice appreciated. HNY to all in the group. 73's

The rig is acting like I am jerking the vfo knob back and forth quickly. Signals jump into the passband and then jump out. When I try to actually tune the VFO knob, it becomes more pronounced.

The audio is not distorted, just jumping back and forth.

After awhile, it seems to calm down and is dramatically reduced but does not disappear completely.

I notice it on all bands SSB tuning region, regardless of mode. But I don't hear it in the CW portions, regardless of mode. Any freq above 250 kHz on a band seems to be the issue

Mark,
It sounds like your VFO wiper needs cleaned. Here is the procedure
for an 820, but is the same for a 520. You don't need to remove the
vfo from the cabinet. Just drop a few drops of DeOxit D5 on the wiper
indicated on page 14 & 15 of the following procedure. After ddoing
this, rotate the dial back and from 0-500 (one end to the other).
Most of the time one applications will fix the problem, but if it
still has problems, do the procedure again.

John:

That is a 6uhy choke. Factory org is a 3 uhy choke. I would go to RF Parts and buy their RFC 3.3uhy 800ma choke.

Also I would replace the RF bypass capacitor even if no discoloration, cracking, or hole blown in ceramic body.

Also have you determined the root cause of failure? Have you checked the bias supply to the tube socket pins? This looks like thermal runaway damage to me. What do the plates of the final tubes look like? Any shiny metal especially at the sharp bends. Any holes melted thru? Any glass envelope suck in?

After rebuild and good cleaning of the bias adjust pot, I would measure and monitor the cut off and operating bias at both control grids at tube socket pins 5 (nominal -100vdc and -55vdc). Suggest you do that with the heaters turned off and if proper operating bias voltage level can be set and is smooth and stable then Ok to turn on heaters and set the zero signal plate current in SSB mode to 60ma.

Roberts,

Please add your name at the end of messages you post on the group.

Remove the 3 screws holding the bottom plate to the D104 Silver Eagle microphone stand. You will see the microphone wiring on the bottom cover plate.

I recommend you change the wiring to bypass the amplifier in the base of the microphone, its not necessary to use it with the KW hybrids since the KW hybrid have more then enough transmit audio.

The microphone plug wiring for the TS-520SE is found in the TS-520SE user manual on page 6 and the schematic on page 41. If you do not have the TS-520SE user manual then you can download it from my website us9ng the following link:

http://w5rkl.com/manuals/ http://w5rkl.com/manuals/

When the page comes up, scroll down to the Kenwood listing and click on the TS-520SE "Instruction Manual" link.

I highly recommend you do not use the same grounds for PTT and the microphone element. Separate the PTT and Microphone element grounds.The Silver Eagle microphone switch can be easily wired so the 2 grounds are separate. The PTT ground is pin 3 and the microphone element ground is pin 4.

Jack:

With the Plate Load cap plates fully meshed (knob turned full CCW) and in Tune mode can you get the initial plate current dip?

There are two fixed padder caps (82 pf and 47 pf) switched in across the Plate (Tank) capacitor on 80 and 40 meters respecitvely. The contacts are on deck S5-1 of the bandswitch.

The caps can be accessed by removing the front Final tube. One lead of each one is terminated on the Neutralizing capacitor stator post and the other lead goes to the BS contacts and can be accessed by removing the metal shield plate at the back end of the BS shaft.

Would be unusual for both padder caps to be bad and for both BS contacts to be bad. If you have an LCR bridge can place BS in 20 meters or higher position and measure each cap. Can also look at them to see if showing any signs of overheating, but measuring is better test.

The BS contacts can be cleaned by removing the 3 screws that hold the metal shield plate at the end of the BS shaft.

56311. TS520S "TUN" problem

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2016-12-31 17:18:06 UTC
From: chrishender@...
Topic: 56311 Message: 56311

Hi everyone, my first posting so I hope I do this right.

The problem is with my TS520S owned new by my me so no silly mods etc.The rig works really well for ages and then when switching to "TUN" all goes dead.

There is no audio signal although the meter is kicking indicating that signal is there. Amplifier background hiss is there which increases/ decreases with volume control.

Rig will not tune for transmit with no ALC reading even when DRIVE is rocked to and fro so impossible to tune. Leaving it switched on for a few minutes and eventually it all springs back into action as if

there is no problem at all. When in fault condition switching to USB on 20 metres and transmit/ receive works fine but obviously I cant change band to retune as "TUN" position doesnt work.

My course of action so far has been: Checked both relays by swap and then returned to original places, sprayed SW3 with switch cleaner and visually inspected for problems. Replaced all resistors on HV board,

checked voltages on Rectifier unit as per manual.Replaced all electrolytics on all boards.The rig will go for a few days with no probs and just as I think the problem has gone it comes back again! Very frustrating

so if anyone has any ideas I would be grateful. Many thanks in anticipation. from Chris G4HYV.

Jack:

If it turns out that the Tank cap padders are good and being switched in on 80 and 40 the other possibility is bad padder caps and/or bad BS contacts for the Plate Load air variable cap. If those padder caps arent being seen then it would be same as if you had opened the plates of the Plate load cap full un-meshed. Would be no or very little discerbable plate current dip and heavy Ip coming out of the gate.

This is a little easier to troubleshoot without test gear. Can install a coax tee on the SO-239 and tack solder a 680pf cap on a PL-259 connector and screw on the open Tee. If can now dip and load near normal you know the problem is not with the two Tank cap padders and/or BS contacts.

Jack:

With the Plate Load cap plates fully meshed (knob turned full CCW) and in Tune mode can you get the initial plate current dip?

There are two fixed padder caps (82 pf and 47 pf) switched in across the Plate (Tank) capacitor on 80 and 40 meters respecitvely. The contacts are on deck S5-1 of the bandswitch.

The caps can be accessed by removing the front Final tube. One lead of each one is terminated on the Neutralizing capacitor stator post and the other lead goes to the BS contacts and can be accessed by removing the metal shield plate at the back end of the BS shaft.

Would be unusual for both padder caps to be bad and for both BS contacts to be bad. If you have an LCR bridge can place BS in 20 meters or higher position and measure each cap. Can also look at them to see if showing any signs of overheating, but measuring is better test.

The BS contacts can be cleaned by removing the 3 screws that hold the metal shield plate at the end of the BS shaft.

I did some more cleaning of the pots and switches, also adjusted the balance on the Generator board again. USB seems to be fairly stable now aside from an initial pulse of power for a split second with I start transmitting (settles at normal bias current after an initial spike, Does not happen on LSB). I have made several contacts and received good reports.

I am not going to worry about the CW car control thing. The knob is a bit fiddly but I can bring the output to 200ma of IP for that mode per the manual. Maybe that's normal, No idea.

I think it's working well enough. Thanks.

Nick, AC9LF

Many thanks Mike.

Very well said.

Best to you too.
